It is reported that the Advisory Council of the Association for Preventing the Re-enactment in the State of New York of the Present Code of Ethics of the American Medical Association has determined upon publishing a volume designed to influence the profession in favor of the object of the association. If the book is strictly argumentative, it will doubtless answer the purpose intended; if, however, it contains passionate appeals to State pride, if it pays much attention to side issues, and, above all, if it is intemperate or even warm in its allusions to the American Medical Association or to individuals, it will tend to defeat the object in view.

It is stated, also, that the council intends to publish evidence that some of the prominent supporters of the old code have made a practice of consulting with homœopathic practitioners. We do not hesitate to say that, if this course is pursued, the association will at once lose the support of those who are willing to work for the principles at issue on the plan thus far followed, but who would turn from that work with disgust the moment it became evident that tactics of this sort were to be brought into play. In our opinion, the council can not be too careful in its communications to the profession.

COPPER AS A PROPHYLACTIC OF TYPHOID FEVER.

M. BURQ, of "metallo-therapy" fame, has brought to the attention of the Paris Academy of Sciences certain considerations which show, he thinks, that workmen in copper acquire a decided immunity from typhoid fever, or at least an unusual capability of recovering if attacked by that disease. Taking the mortality from typhoid fever as 1.3 for every thousand of the population during the recent epidemic in Paris, he remarks that at the same rate the disease ought to have caused fifty-two deaths among workers in copper, even including in the estimate of their number all whose connection with the business is merely nominal. In point of fact, only thirty-nine such deaths occurred, and, by a process of exclusion which he seems to regard as justifiable, M. Burq reduces the number to three. Even in two of those instances circumstances are mentioned that he thinks tended to interfere with the protective influence of the copper. Curiously enough, in one of them a "deplorable" hygienic environment is suggested as having overcome the salutary action of the copper, while in the other one the exceptionally good ventilation of the workshop is thought to have diluted the cupreous emanations to such a degree as to render them inadequate to the effect they would have produced under ordinary circumstances.

A PHYSIOLOGICAL PARADOX.

M. KANELIS recently discovered accidentally that section of the sensory root of a spinal nerve seems to result in a notable exaltation of the excitability of the motor root. The experiment is as follows: Laying bare the whole medullary canal of a frog, the roots of all the nerves are divided, save only the motor and sensory roots of one nerve. The motor root is now stimulated with the faradaic current, and the strength of the current is reduced to the minimum at which it produces any appreciable effect. The coil is then disconnected, and the current becomes too feeble to excite contraction. On dividing the sensory root, however, the same current provokes energetic contraction.

Proceedings of Societies.

NEW YORK SURGICAL SOCIETY.

(Continued from page 552.)

HYGROMA OF THE TONGUE.—Dr. GEESTER presented a specimen of congenital hygroma of the base of the tongue removed from a girl thirteen or fourteen years of age. This cystic swelling was noticed quite early in life. The child was brought to him by Dr. F. Serr. He found a tumor of the size of a rather large English walnut, occupying the most posterior portion of

the left side of the tongue, extending about two thirds of the length of the tongue forward, and reaching posteriorly to the anterior pillar of the fauces. By a puncture and examination of the contents, he diagnosed hygroma. Finding that the empty sac had rather thick walls, and recollecting that he had had an unsatisfactory experience in treating these tumors by any of the methods commonly employed, he decided to lose no time, but to attack the growth and remove it entirely. He first ligated the lingual artery; he then held the mouth open by the use of Whitehead's speculum. A fillet was passed through the base of the tongue, and with this the organ was pulled well forward. The tumor was then exposed by an incision carried along the edge of the tongue, and the sac excised by means of the forceps and a pair of scissors. The hemorrhage was so very slight that the excision could be performed rapidly. The cavity was mopped out with a five-per-cent. solution of carbolic acid, and the edges of the wound were stitched together with very fine silk. He carried the incision along the edge of the tongue purposely, in order to bring it into the portion of the oral cavity where the dressing could be retained without difficulty. A piece of gauze powdered with iodoform was placed between the tongue and gums opposite the line of incision, and it was retained in that situation for thirty-six hours. When it was cast out, the wound was found without irritation and united. Likewise did the deligation wound heal by first intention. The subsequent progress of the case was very favorable, and the child was dismissed from the hospital, cured, on the fifth day. He thought that complete extirpation of these growths was the most advisable method of treatment, especially for dermoid cysts, which occasionally grew in this locality.

URETHRAL CALCULUS.—The President presented a specimen of urethral calculus, together with a fragment of a flexible catheter taken from a man sixty-nine years of age, who had suffered for thirty years with vesical symptoms, which during the past ten or fifteen years had been supposed to be due to the presence of a calculus somewhere in the urinary passages. Shortly before the patient came under Dr. Markoe's observation he presented himself to a physician residing outside of the city, complaining of symptoms of stone in the bladder, such as irritation, passage of blood, and stoppage of the stream, and the doctor had detected a stone in the course of the urethra. He then passed his instrument into the bladder, and, as he thought, detected a stone there. The case was interesting because it illustrated the uncertainty of the vesical exploration, as would be subsequently seen, when a stone existed in the urethra. The physician stated that he could feel a stone distinctly on either side as he turned the point of the instrument within the bladder. Further manipulations were resorted to for the purpose of removing the stone in the urethra, which was situated just at the peno-scrotal junction. The doctor tried in various ways to get rid of it, but did not succeed. He then hit upon the expedient of taking an elastic catheter, cutting a piece out of one side, and then passing it beyond the stone, hoping that the opening in the side would allow the edge of the stone to engage in it so that he could pull it out. The idea was correct mechanically, and it caught the stone, but, in trying to extract it, the extremity of the catheter was pulled off and left posterior to the calculus. In that condition the patient presented himself at the New York Hospital. Dr. Markoe found the stone in the urethra, but was not able to form a definite opinion with regard to the existence of a stone in the bladder, nor could he ascertain the position of the fragment of catheter. He therefore proceeded as if it might be possible that a stone existed in the bladder, also thinking that it was quite probable that the end of the catheter had entered the bladder. He made an incision as for the median section in lithotomy, and introduced the finger into the

bladder for the purpose of exploration. At this point it occurred to him to avail himself of the opportunity to test the suggestion made by Sir Henry Thompson that the inner surface of the bladder could be explored with the greatest facility by the finger for the detection of calculi, tumors, etc., and he therefore instructed himself with reference to this point, and found that he was able, with the greatest ease, to ascertain exactly any irregularity or any roughness upon the inner surface of that viscus. He found nothing in the bladder, neither stone nor piece of catheter. The inference, therefore, was that the catheter was anterior to the opening in the urethra, which was made in the membranous portion. He therefore extended the incision forward slightly, passed the forceps forward, and first seized the little piece of catheter, and then, passing the instrument a little farther on, came upon the stone, seized it, and removed it. No bad symptoms followed the operation, and the patient was discharged from the hospital at the end of two weeks.

WOUND OF THE INTERNAL JUGULAR VEIN; LIGATION, EXCISION, RECOVERY.—The President also presented a glandular tumor, which merely served as a text for the recital of the history of the case in which an operation was performed for its removal. The case was one of lymphoma of moderate size occurring at about the middle of the left side of the neck in the chain of lymphatic glands behind the sterno-mastoid muscle. He made his incision so as to reach the tumor behind the sterno-mastoid, and, partly cutting and partly enucleating, without much difficulty reached the deeper portion of the tumor; but when this point was reached it was found that the growth projected forward and beneath the sterno-mastoid muscle, and he was obliged to draw the entire mass backward and outward in order to effect its removal. In so doing, it became very difficult to be certain as to exactly what he saw and what was divided in separating the attachments of the base of the growth. When the tumor was nearly separated he was suddenly shocked by the occurrence of a hæmorrhage which was something terrific. It was evidently venous blood, and was pouring out from the bottom of the wound in a stream as large as his little finger. Instantly he plugged the wound with sponges, and then the difficulty was to get at the bleeding point, which evidently was either the jugular vein or some other vein of large size. For one moment he heard a hissing sound, but he was not certain whether it was actually due to the entrance of air into the vein or not. After a little time, constant pressure upon the bleeding point being continued, he carefully and slowly withdrew the sponge, constant pressure also being maintained both above and below, and was able, after several trials, during which much blood was lost, to first catch with the forceps the anterior source of the hæmorrhage and pass a ligature about it. Bleeding from this point was arrested permanently and perfectly. Then the posterior and deepest portion of the wound was dealt with in the same way, and he finally caught a large portion of tissue, including the bleeding point, and threw a ligature about it, when the hæmorrhage ceased. When this had been done, he found that the point from which the hæmorrhage came was just above the bifurcation of the common carotid artery, and the bleeding was evidently from where the lingual and superior thyroid veins unite and empty into the jugular vein, and he had tied these vessels; the other ligature was found to be on the side of the internal jugular vein. It was tied firmly, but he felt unwilling, and so he had always felt, to leave a lateral ligature on the jugular vein. He therefore dissected the parts carefully, exposed the vessel perfectly and clearly, put a ligature around it above and below, and cut off a piece between, partly to release the tension and partly because he wished to see the lumen of the vessel in order to be sure of what had been done. The points of the severed vein were now at least two inches distant from each other. The wound was left

open to heal by granulation. The progress of the case was most favorable, and the patient was now perfectly well, no unfavorable symptom having developed, nor local hæmorrhage having occurred. Dr. S. W. Gross had collected the largest number of cases of ligation of veins, and had recorded fatal results in twenty-two out of one hundred cases, the fatal results being largely due to phlebitis and septicæmia. Of these twenty-two cases, in five the patients died of secondary hæmorrhage, and it was a singular fact that in every one of these five cases the ligature had been applied to the side of the vessel. No death had occurred from secondary hæmorrhage in any case included in his tables from ligation of the vein in its continuity or at its cut extremity. Dr. Markoe believed that the proper plan to pursue was to throw a ligature completely around the vessel, and to leave the wound open, to heal by granulation.

FRACTURE OF THE BRIDGE OF THE NOSE.—Dr. ALFRED C. POST was consulted two weeks ago by a young lady from Michigan who had a deformity of the nose caused by fracture of the bridge. The nose was extremely flattened. He made an incision on each side, opposite the sutures between the nasal bones and the superior maxilla, with the chisel separated the bridge, and then, introducing a firm director, brought them up into place as nearly as possible. The wound was progressing favorably, and there was a marked improvement in the deformity, although it had not been entirely corrected.

Dr. WEIR remarked that he had found it desirable in a number of cases to fracture the central portion first from within, and then to separate the nasal bones from the maxilla by the chisel, when the fragments could be readily put in proper position and easily retained there.

A STATED meeting was held April 24, 1883, T. M. MARKOE, M. D., President, in the chair.

LYMPHANGOMA OF THE SKIN.—Dr. F. LANGE presented a patient, a girl thirteen years of age, whom he first saw about three months ago. When three years old the mother first noticed in the axillary region a spot, about the size of a silver quarter of a dollar, which had a reddish color. Since that time the spot had slowly but gradually increased in size, and during the last year it had grown quite rapidly. When Dr. Lange first saw the patient there was quite an extensive growth in the axilla, consisting of an elevation of tissue something of the shape of a horse-shoe, with some irregular attachments, and on the whole presenting an appearance not unlike condylomata. The excrescence-like growth occupied a space about five to six inches in length, varying from half an inch to an inch in width, and from a half to three quarters of an inch in height. Besides this more massy growth, there were quite a number of small, whitish vesicles spread over the skin in the neighborhood, apparently containing fluid, and, when the entire growth was examined very carefully, it was evident that the more prominent parts were made up of an agglomeration of these small vesicles, forming an apparently papillary growth, and between these numerous large blood-vessels could be seen. Dr. Lange excised the upper part of this tumor, leaving behind, however, a number of these disseminated, small, whitish vesicles, because he thought that the wound would be too large if all the skin on which these vesicles were situated was removed. Besides, he hoped to obliterate these isolated points by some other method of treatment. The operation was performed eleven weeks ago. A wound almost of the size of the hand was left, but it had healed comparatively smooth, suppuration occurring only in a few places. About four weeks ago he noticed that in the scar these little whitish vesicles had reappeared, and they could be distinctly seen on close inspection, and, when punctured with a needle, a clear fluid could be pressed out. The actual cautery had been applied once

upon the disseminated vesicles, but in the scars vesicles had reappeared. At present he advised the local application of the stronger tincture of iodine. The growth was located exclusively in the cuts. In the deeper parts of the skin there was at one point a thick mass which looked not unlike elephantiasis. The blood-vessels were so much developed that it was necessary to apply quite a number of ligatures at the time of the operation.

He had noticed that Kaposi, in his recent work, mentioned only one case that he had seen. Dr. Lange thought that the vesicles were due to distension of the lymphatic spaces, and believed that the vesicles on the cicatrix were due to the same change. He had operated in one other case, that of a small child, who had a similar growth upon the side of the thorax. In that case the subcutaneous tissue was somewhat involved. He had also seen another case which was operated upon by Professor Esmarch. In both of these cases, however, the skin was not involved to such an extent, and complete extirpation in healthy parts could be performed with lasting success.

Absorption of Zinc from the Local Use of a Solution of Chloride of Zinc in the Treatment of a Burn; Nephritis.—Dr. L. A. STIMSON presented mounted microscopic specimens of the kidney, which, together with the history, were furnished by Dr. W. L. Wardwell, house surgeon at Bellevue Hospital.

Robert W., aged four years, a quadron, of feeble constitution, was admitted to Ward 1, Bellevue Hospital, January 2, 1883, suffering from a scald of the back and side, which included the left side of the back to within one inch of the median line, extending from the third dorsal vertebra above to the second lumbar below, the left side of the chest and the left anterior surface of the abdomen, the left axilla, and the lateral abdominal region below it. It extended down upon the anterior surface of the left thigh for three inches, and over the left acromion and lower part of the posterior surface of the neck. The scald differed in severity in the several localities. Upon the thigh and over the shoulder, and for a space of two inches at its edges, only the epidermis was injured; in the axilla, just below it, and over the back at the same level, the entire thickness of the integument was compromised.

The patient suffered at the time of the injury from shock, from which he reacted. The burns were dressed with carbolized vaseline spread upon strips of sheet lint, this being surrounded with cotton, and the whole secured by a bandage. The injured tissues sloughed extensively. The dressings were changed as often as necessary, and the patient's general condition was carefully attended to. His temperature during this period fluctuated from 99° F. in the morning to 102° in the evening. On January 28, 1883, it was normal for the first time. It remained so for a few days; after that he rarely passed a day without an evening exacerbation of from one to two degrees. At the end of five weeks the sloughs had entirely separated, and the ulcer resulting was covered with small healthy granulations. During the following month the edges of the ulcer healed very rapidly, and upon March 2d, two months after the injury, the original ulcer had diminished its dimensions one half. During the next week the reparative forces appeared to be at a standstill, and during the two weeks following the newly formed cicatricial tissue broke down extensively, the ulcer regaining nearly its original dimensions. The patient complained of pain, and seemed to be relieved by frequent dressings. At these dressings the ulcer was sprinkled with a thin layer of iodoform, and then covered, as before, with sheet lint spread with carbolized vaseline. About this time the urine was examined, as it had been when the patient first entered the hospital. No albumin or casts were found. Under this form of treatment no improvement took place. The appearance of the ulcer betokened a sluggish action; its edges were sloping and adherent; the lower portion was dotted with small

islands of cicatrization, which had persisted while the surrounding tissue had broken down; the granulations were bluish in color, flabby, and did not bleed readily.

Upon April 4, 1883, the patient was etherized. The ulcer was washed with four ounces of a five-per-cent. solution of chloride of zinc. There was no cavity or pocket in which any of the fluid could be retained. A dressing was applied, consisting of three pads of *dry* carbolized gauze, each composed of six thicknesses of the gauze. These covered the ulcer only. Over these were placed eight layers of gauze, and one layer of Macintosh completely surrounding the body. The entire dressing was kept in place by numerous turns of a carbolized bandage. The patient vomited several times before the administration of the anæsthetic; this was attributed to some error in diet.

While reacting from the anæsthetic the patient vomited several times during the afternoon and evening. During April 5th he was either drowsy or sleeping most of the day. He appeared to be completely free from pain, and, upon being questioned, replied that he felt well. His pulse was as good as before the dressing, and his changed behavior, which had been exceedingly irritable, and his freedom from pain, were subjects of congratulation, and were attributed to the good effects of the dressing. The patient seemed to be easily nauseated, and vomited several times. He was placed upon a milk diet, and bismuth was administered to check the vomiting. His temperature was, 10 A. M., 97.5° F.; 10 P. M., 99° F.

During April 6th the patient's general condition was much the same. His nausea persisted, but to a lesser extent. His temperature was, at 9 A. M., 97.5° F.; 9 P. M., 99° F. In the evening the nurse reported that he had passed no urine for twelve hours. A poultice was placed over the abdomen, and pieces of ice were put into the rectum. Two hours later he passed four ounces of urine. This specimen was analyzed the following day. Color, greenish black; whitish sediment. Specific gravity, 1.020. Decidedly acid. Albumin one third of bulk. Mr. Rice, the chemist at Bellevue Hospital, examined it chemically, and found that it contained zinc in a considerable amount. It was not tested for carbolic acid. During the twenty-four hours of April 7th the patient passed six and a half ounces of urine of the same characteristics as that found upon the 6th. A microscopical examination showed the presence of a few epithelial casts. The patient was placed upon the infusion of digitalis, and the region of the kidneys and bladder was poulticed. The pupils were not contracted.

Temperature, 9 A. M., 98.25° F.; 6 P. M., 97.5° F. The patient did not vomit but once, retained milk, six ounces, and a small amount of rice and milk.

April 8th.—The patient passed 5.5 ounces of urine, lighter in color than that passed before, but still decidedly greenish, and containing a large number of casts of all varieties. He vomited several times during the day. Otherwise his general condition was much the same. Temperature, 9 A. M., 98°; 1 P. M., 101°; 5 P. M., 100°.

April 9th.—The patient complained that his back hurt him, and, as the discharge had come through the dressings at several points, a new dressing was applied. As a result of the stimulation by the chloride of zinc, the character of the granulations had changed: they were decidedly more healthy and firm in appearance. The edges of the ulcer were making an effort at repair. At this dressing the surface of the ulcer was not disturbed by washing, and the *dry* pads of carbolized gauze were applied directly to its surface, as before. After the dressing the patient was much more comfortable. Temperature, 9 A. M., 98°; 5 P. M., 98°. He vomited several times during the twenty-four hours. He passed during the same period seven ounces of urine.

April 10th.—At 6.30 A. M. the house surgeon was called by the nurse, who reported that the patient's temperature was 95.5°. He was visited immediately; was found quiet; answered rationally; pulse rather more feeble than usual. He was surrounded with hot bottles, and given whisky, one ounce, with orders to the nurse to repeat the whisky in fifteen minutes, and report in half an hour if the temperature did not rise. Half an hour later the nurse reported that the patient was still cold, and screaming with pain. The house surgeon immediately went to the ward, but before reaching it the patient had died. The seven ounces of urine which the patient had passed April 9th was examined chemically for the presence of zinc; none was found. The color, which was darker than on the two days preceding, was found to be due to the presence of carbonic acid. Albumin was present in large amounts, and casts of all varieties were more abundant than in any of the specimens previously examined. At no time during the course of the disease did the patient show any signs of œdema, nor was he attacked by convulsions. A complete autopsy was not permitted. One kidney was obtained; weight, 4.5 ounces. Capsule non-adherent, light in color, cortex swollen, stripings not distinct. Microscopically, the glomeruli are smaller than normal, either from pressure or contraction. Between them and the capsule there are decided spaces, which in some instances contain large cells, nucleated, suggestive of a glomerulonephritis. The cells lining the capsule are swollen and thickened, and, to a certain extent, desquamated. The capsules are thickened, probably the result of an œdema of the stroma. The convoluted tubes are in many situations enormously dilated, showing probable fatty changes in the epithelium, and desquamation of the latter. A number of the tubes contain hyaline, epithelial, and blood casts, and some few pus-cells, but these are by no means frequent. Some of the tubes contain a detritus which is suggestive of a pre-existing hæmoglobinuria, but this was not discovered during life. There are several foci of small cell-infiltration, especially well marked in the vicinity of the blood-vessels.

Dr. STIMSON also presented a specimen which illustrated BONE LESIONS OCCURRING AT A DISTANCE FROM A JOINT, BUT APPARENTLY PRODUCED BY ARTICULAR INFLAMMATION.

The specimen consisted of the lower portion of the femur and the upper portion of the tibia, removed by amputation from a man who entered Bellevue Hospital on the 9th of April, 1883. He was thirty-two years of age, and stated that in October, 1881, he received a charge of buckshot just above the left knee; that five or six of the shot perforated the thigh from without inward; that two passed through the bone, four passed through the soft parts, and all but one made a complete passage through the limb. The sixth shot was cut out. He had been treated in various hospitals, and had undergone several operations under ether, at some of which, so far as could be ascertained, bone was removed from the lower end of the femur, and the evidence remained of an incision having been made on the inner and outer side of the thigh. Three weeks before admission to Bellevue Hospital, while in a city hospital, a phlegmon developed over the upper and inner portion of the tibia on the same side. It was cut into by a straight incision, the periosteum was found thickened, and exit was given to a small quantity of pus which was between the periosteum and the bone. At that time the man desired amputation, but it was not performed, and he left that hospital and came to Bellevue and asked that his limb should be taken off. There were two openings—one on the outer and the other on the inner side of the thigh at its lower part, and a third opening made by the operation three weeks ago over the upper part of the tibia. The probe could be passed completely through the thigh at its lower portion, but no bare

bone was detected. Bare bone, however, could be detected through the opening made over the tibia. Amputation was decided upon, and was performed by Dr. Wardwell, at a point about four inches above the joint. After the limb had been removed, the bones were sawed longitudinally, and presented the following appearances: The femur above the condyles was enlarged by subperiosteal thickening. About an inch and a half above the joint there was an opening in the bone which passed completely through from one side to the other, and its surfaces were covered with granulations to such an extent that bare bone could not be detected at any point. The knee joint was completely obliterated by fibrous adhesions between the opposing articular surfaces, so that there was only a very slight amount of motion in it. The tibia, at about an inch and a half below the articular surface, showed a central abscess, situated immediately beneath the incision which was made in the periosteum three weeks previously, and before admission to Bellevue Hospital. It was separated from the external surface by an intact layer of compact bone. Two days before the operation the patient complained of soreness in this region, and the limb presented the signs of phlegmonous inflammation at a point corresponding to the tubercle of the tibia where the extensor muscles are attached; and here a small opening in the bone was found, leading into the abscess. In the head of the tibia there were two hæmorrhagic foci, neither of which had suppurated. There was a third hæmorrhagic focus below the abscess first mentioned. The patient thus far was doing well.

NEW YORK MEDICAL AND SURGICAL SOCIETY.

A STATED meeting was held December 9, 1882, Dr. T. GAILLARD THOMAS, President, in the chair.

ORCHITIS AND EPIDIDYMITIS RELIEVED BY THE DIVISION OF URETHRAL STRICTURES.—Dr. F. N. OTIS related several cases of this sort. [They will be given in a future number of the journal.]

Dr. R. F. WEIR remarked that neuralgia of the testicle most frequently occurred from prostatic or bladder trouble, or from congestion in the prostatic region arising from ungratified sexual desire, or from the passage of an instrument through the deep portion of the urethra. Milder measures, therefore, should first be tried than division of the meatus.

Dr. OTIS thought that no method of treatment could be adopted which was less dangerous than the division of strictures in the anterior portion of the urethra, and that this should first be tried rather than the immediate passage of a sound through the deep portion of the urethra to determine whether the trouble might lie in that region, for it was well known that the passage of instruments through this portion of the urethral canal often gave rise to serious trouble.

Dr. A. C. POST remarked that he had never seen any ill result from the division of a contraction in the anterior portion of the urethra, but he had known it often to be productive of good results. If an hypospadias were made, it was the fault of the surgeon.

EXTREME PELVIC PAIN, PROBABLY DUE TO RUPTURE OF A TUMOR OF THE FALLOPIAN TUBE.—Dr. T. F. COCK had been sent for recently to see a woman in great agony from darting pains radiating over the abdomen from a point in the right iliac region. The trouble commenced suddenly while she was stooping, lacing her shoes. Relief was not obtained until after forty-eight hours, when ten grains of morphine had been administered hypodermically and by the mouth. The temperature and the pulse rose very little, if any, above normal. The stomach rebelled against food. The patient had become so weakened at the end of the forty-eight hours that it was feared she could not re-

cover. By the use of stimulants, however, she had begun to improve. Dr. Cock could not account for the cause of the trouble, but stated that one of the patient's sons, twelve years of age, had fainting attacks at times, since they had moved into their present dwelling; another son had been incapacitated for business by headache and general weakness; families who had lived there previously had removed because of sickness. Possibly all these troubles had originated from the emanations from large accumulations of the excrement of rats found about the water-pipes.

The President had seen several similar cases in which he had made the diagnosis of rupture of a cyst of the Fallopian tube. A girl, about nineteen years of age, presented herself at the Woman's Hospital for treatment of a greatly enlarged clitoris, which was probably of syphilitic origin. About ten days after its removal, while she was rising from bed, agonizing pain suddenly developed in the iliac region on one side. Peritonitis set in within twelve hours, and the patient died. At the post-mortem examination it was found that there had been a pyo-salpinx, of about the size of a duck's egg, which had ruptured and emptied its contents into the peritoneal cavity. In the other cases which he had observed the patients recovered so that the diagnosis could not be verified by a post-mortem examination; the symptoms, however, were so definite that he had no doubt that rupture of a fluid tumor of the tube, filled with pus or blood, had taken place. The pain in these cases developed suddenly, was agonizing, and large quantities of morphine were required to allay it. The temperature and the pulse were little elevated unless peritonitis was present.

Dr. Post asked if it was not better to combine the inhalation of chloroform with the administration of morphine than to give the latter drug in such large quantities. He had often found such a combination of the two drugs to be efficacious when large doses of morphine alone failed to give relief.

CARCINOMA OF THE COMMON BILE-DUCT.—Dr. F. DELAFIELD had recently reported a case to the society in which the question of aspiration of a dilated gall-bladder arose. The patient died a few days later, and the cause of the changes was found to be carcinoma of the common bile-duct. This constituted the fifth case of carcinoma of the common bile-duct which had come under his observation, and, as the disease occurred rarely, the facts common to the five cases were related as follows:

Five cases occurred in males. The patients were of the ages of thirty-five, fifty-one, forty-seven, fifty, and forty-eight years respectively; in three cases the duration of the disease from the commencement of the symptoms was three months, in one case two months, in the other only one month. Two of the cases were preceded by chronic dysentery. Jaundice, which developed very rapidly, and progressed throughout the course of the disease, was the first symptom in all the cases. In two of the cases, with the development of the jaundice, attacks of severe pain occurred in the epigastric region. In all there was loss of appetite, nausea, and vomiting. After the disease had become established, all of the patients emaciated rapidly. In one case the attacks of pain were repeated throughout the course of the disease. In three there were bleeding from the gums, vomiting of blood, passage of blood from the bowel, and extravasations of blood into the skin. In only one case was there febrile movement, and in that instance it was probably due to suppurative inflammation of the bile-duct. It was found at the post-mortem examination that the tumor of the bile-duct was not sufficiently large in any of the cases to enable one to make a diagnosis. In two of the cases there was simply an infiltration of the walls of the duct with cancerous material. In all, the new growth seemed to have originated in the mucous glands in the walls of the bile-duct, and had the characters of an epi-

thelial cancer with cells of the cylindrical variety. In two cases the new growth had extended to that portion of the pancreas immediately beneath the bile-duct, infiltrating its tissue to a moderate extent. In one case there were secondary nodules in the lungs. In none of the others had metastatic growths occurred in other parts of the body. The liver was considerably increased in size in four of the cases; in one it was of about normal size. In only one case was there perceptible dilatation of the gall-bladder. In one case there was catarrhal inflammation of the bile-duct, with suppurative inflammation of the adjacent liver-tissue, which had produced small abscesses.

TENDENCY TO THE REPETITION OF MONSTERS.—Dr. H. F. WALKER had recently attended a woman in confinement who stated that, according to her reckoning, delivery should have taken place ten days sooner. Since that time the child had shown fewer signs of life than previously, and just before delivery movements had ceased altogether. It proved to be a monster, and died immediately after birth. The eyelids were partially closed and were adherent to each other, the nose and mouth were deformed, most of the fingers were webbed, a phalanx of one thumb was wanting, the sex could not be determined, and the anus was imperforate. The point of interest in the case was the fact that the woman had been pregnant twice before, both times giving birth to a monster. Dr. Walker attended her in her second confinement, which took place at full term. The foetus resembled a turtle, and had only one eye, and the abdominal walls were wanting. As in the last instance, it simply gasped and died. The woman was out of the city at her first labor, which came on at the seventh month. He was informed that the foetus in that instance was also a monster. Dr. Walker was compelled, at her last confinement, to remove the placenta by hand. It was examined by a microscopist, and was found to contain a great deal of calcareous material, and was very brittle. The woman had suffered with pain in the region of the uterus before delivery. She was healthy, but spare, and somewhat nervous.

SUBCUTANEOUS EMPHYSEMA OF THE NECK AND FACE ATTENDING LABOR.—Dr. J. W. McLANE related the following case: The patient was a primipara, twenty-one years of age. The first stage of her labor lasted two hours, and was characterized by unusually severe pains. So excessive was the uterine action, and the pains were of such long duration, that chloroform was administered, though not to an extent sufficient to render her unconscious. Soon after the commencement of the second stage she began to strain violently, and her efforts were attended with extreme suffering. Although she was urged to desist from all expulsive efforts, and to inhale chloroform freely, it was difficult to produce complete anesthesia. During a violent bearing-down effort, of long duration, her face became congested and of a purple hue, and a swelling made its appearance on the right side of the neck near the trachea, which, on examination, was found to be a localized subcutaneous emphysema. During the next three or four pains, which followed one another in rapid succession, the swelling increased and extended to the right cheek. Labor was terminated very soon after. As soon as the patient returned to consciousness she complained of a constriction in her throat, and experienced some difficulty in swallowing. Her appearance was such as to attract the notice of every one who saw her. Her neck, previously slender, was now thick and oedematous; her face so puffed that on the right side the eyelids were closed, as if by dropsical effusion, and the features effaced. When pressed upon, the puffy swelling gave the characteristic crackling. There was no emphysema below the clavicle. In the course of a few days the swelling gradually subsided as the air became absorbed, and by the end of a week it had entirely disappeared. Dr. McLane remarked that rupture of the

air-passages during labor rarely occurred, giving rise to emphysema, either pulmonary or subcutaneous. He believed that in this case the rupture occurred in the trachea. He had seen but one other case, and in that there was rupture of the pulmonary vesicles.

Dr. Otis had seen, in the neck and cheek, in a young, healthy woman, a localized emphysema, which had taken place while she was engaged in some domestic duties of a light kind. The swelling disappeared. The only possible cause of such an accident in this case seemed to be straining efforts at stool, as suggested by Dr. Weir.

A STATED meeting was held December 23, 1882, Dr. T. GAILLARD THOMAS, President, in the chair.

THE SELF-LIMITATION OF CERTAIN DISEASES WHICH ORDINARILY PROVE FATAL.—Dr. B. W. MCCREADY said that this subject, which had often arisen in his mind, had recently been forcibly impressed by certain cases of phthisis which had come under his observation. Certain members of his own family had in early life suffered under all the symptoms of pulmonary consumption, such as long-continued cough, repeated attacks of hæmoptysis, emaciation, etc., and, on going to a southern climate, had apparently regained perfect health, which continued for perhaps twenty years. At the end of that time there had been a return of the former symptoms—of cough, hæmoptysis, emaciation, fever, sinking in of a part of the chest, and of the physical signs of phthisis. After a time they again apparently recovered, gained strength, and were living at the age of seventy-three or seventy-four years. This experience had occurred to him repeatedly—patients affected with pulmonary phthisis, apparently in the last stage, recovering almost perfect health, and living to an advanced age, or until taken away by some other disease. Another instance was that of a gentleman whom he had now attended for forty odd years. Phthisis had been in the family; a brother had died of the disease, as had also all the children of a sister, and finally the sister herself. Some forty years ago this gentleman had repeated hæmorrhages from the lungs, sinking in under the clavicle, great emaciation, and was apparently about to die. He afterward recovered, grew strong, and seemed in perfect health for a good while. About ten years ago, while residing in France, he had another attack of the same symptoms. The French physicians, recognizing the gravity of the case, thought a voyage might be of benefit. On his arrival in New York, Dr. Metcalfe saw him with Dr. McCready. They both believed that he would not be able to live through the winter. He went to Florida, and from there to California, and was now in New York, to all appearances in perfect health, weighing one hundred and ninety pounds.

The same tendency to self-limitation of disease occurred in affections of the brain. He had not infrequently seen cases in which patients had had paralytic seizures, weakening of the intellect and of the memory—the characteristics of the childhood of old age—yet, after a time, they gradually regained their mental power.

Dr. A. C. POST remarked that a relative of the late Dr. Valentine Mott, who had reached an advanced age, once told him that in early life Dr. Mott had condemned him to certain death from consumption. When Dr. Post saw him he was not a vigorous man, but he had reached an advanced age, a great many years after his doom had been pronounced by Dr. Mott. Dr. Post had an elder brother, who, when growing up to manhood, had all the symptoms which at that time were regarded as clearly indicative of pulmonary consumption. His mother and several of the members of her family had had consumption. One of her brothers and his entire family died of the disease. He had married a woman who was also phthisical. The elder brother

referred to had a cough, with copious expectoration, progressive emaciation, and all of the symptoms which at that time, before physical diagnosis was well understood, were regarded as indicative of phthisis. He went to Europe, and returned after a year, partially restored to health. He afterward revisited Europe, traveling in Greece and other parts in the south, and, after two or three years, recovered entirely. No signs of pulmonary disease remained. He died, at the age of twenty-nine years, of scirrhus of the rectum. A post-mortem examination was made, and no trace of pulmonary disease was found at that time, which was about ten years after the pulmonary symptoms had been present.

THE PRESIDENT remarked that this was a subject which he had thought of very much in connection with cancer, including under that term sarcoma, rodent ulcer, etc. It was remarkable how differently cancer of the uterus behaved in different patients. Twenty-five years ago, when patients presented themselves with cancer which had almost destroyed the neck of the uterus, it was his custom to make a very fatal and limited prognosis. At present, however, he was very cautious about doing so, for, although the result was always the same in the end, it was extraordinary how some of the cases would continue. He had known such cases to go on for six or seven years, the patients finally succumbing to the disease which had existed during that long period. He remembered one case distinctly—that of a lady who came on from Galveston, Texas. When he saw her she was almost completely exsanguinated, having been brought on a bed, bleeding almost all the way from Galveston. Upon making an examination, the vagina was found to be filled with some material, which proved to be tannin clotted with blood. It had been used by her physician to stop hæmorrhage, and her relatives had afterward applied it in this liberal manner. Dr. Thomas made a diagnosis of malignant disease, applied nitric acid, and the patient returned home. Her husband had doubted his diagnosis. Returning five years afterward with his wife, he asked Dr. Thomas if he remembered them. Dr. Thomas replied that he remembered the gentleman, but not the lady. The lady was his wife, the gentleman said, and asked Dr. Thomas triumphantly what he now thought of the patient on whom he had pronounced a diagnosis of cancer five years ago. Upon examination, the entire uterus was found to have been destroyed by the disease, which resembled corroding ulcer, there remaining a mere shell of parenchyma with peritonæum. Her physician had been passing a cylindrical speculum right up into the uterus when making examinations, and had stated that the disease had all disappeared. The woman lived two years longer, and then died of peritonitis. It had so often occurred that patients having malignant disease of the uterus continued to live some years afterward, and had therefore doubted the correctness of the physician's diagnosis, that he had referred to the fact in the last edition of his work on the diseases of women.

Dr. MCCREADY spoke of the case of a woman about fifty years of age who had typical scirrhus of the breast. Dr. Weir removed this tumor, and remarked at that time that the patient would probably die within six months. That was five or six years ago, and she was still living, in perfect health, engaged in manual labor.

THE PRESIDENT further remarked that a lady who had epithelioma of the cervix uteri had been visiting him about once a month for three years. There was some hæmorrhage, which seemed to be checked by the application of chemically pure nitric acid. As the disease advanced there was tendency to closure of the vagina. As Dr. Post had suggested, it belonged not to the class of true cancer, but to the milder form of epithelioma.

POLYURIA AS A SYMPTOM OF GRANULAR DISEASE OF THE KID-

NEYS.—Dr. A. B. BALL related the following case, in which it had been difficult for a time to decide whether the polyuria was due to renal disease or to spinal irritation: The patient, a woman sixty-eight years of age, whose general health had been good for several years, was injured in the back last September by falling from a stool and striking on the arm of a chair. Within a few weeks marked spinal irritation developed, especially over the dorsal and lumbar regions, with exquisite cutaneous hyperæsthesia, intercostal neuralgia, and neuralgiform pains in various parts of the trunk. There were no symptoms of myelitis or meningitis of the cord. The case was treated as one of lumbago by a prominent homœopathic practitioner. During the next month her health continued to fail, and shortly before she was seen by Dr. Ball she had had an attack of gastric disturbance, with vomiting lasting four or five days, and apparently the result of overfeeding. This symptom had ceased when Dr. Ball assumed charge of the case. Dr. Austin Flint saw the patient in consultation shortly afterward. She was then passing from eighty to ninety ounces daily of very pale urine of a specific gravity of 1.008 to 1.010. No albumin or casts. No marked arterial tension. As the patient was very stout, the existence of hypertrophy of the heart could not be determined. No valvular murmur. In the absence of positive indications of renal disease, it became a question whether the polyuria was to be regarded as a symptom of degenerative changes in the kidneys, or was to be ascribed to the influence of spinal irritation. The result of treatment seemed for a time to confirm the latter view. Under the use of the ascending galvanic current to the spine daily, the pains diminished in intensity, and the digestive functions improved, while at the same time the urine decreased in amount to about forty ounces daily, its color deepened, and the specific gravity rose to 1.012 and 1.014. A few days afterward the occurrence of a slight convulsion cleared up the diagnosis. The patient, while at stool, and without any previous warning, became momentarily unconscious, and there were slight convulsive movements of the arms. The urine was found to contain a trace of albumin, and a few hyaline and granular casts. Two more similar attacks occurred on the two following days, neither of them lasting more than two or three minutes. After the third attack the patient became soporose, the stomach too irritable to retain food or medicine, and the urine fell to twenty ounces in twenty-four hours. Fomentations with infusion of digitalis were applied to the abdomen, with the effect of temporarily increasing the amount of urine; but the stupor steadily deepened into coma, and death occurred in about forty-eight hours after the third attack.

The PRESIDENT asked whether any of the members had known pilocarpine, administered either by the mouth or hypodermically, to re-establish the secretion of urine in cases of suppression. He thought of trying it in a case in which complete suppression had occurred within forty-eight hours after the removal of a large ovarian tumor, and in which frequent hypodermic injections of digitalin had proved of no benefit whatever. |

ELEPHANTIASIS GRÆCORUM.—Dr. G. G. WHEELLOCK presented a patient suffering with elephantiasis Græcorum. A colored man, by occupation a cook aboard ship, had been in the Colored Home in this city since 1878. The symptoms at that time were such that syphilis was suspected, although the patient denied any venereal infection of which he was aware. He then complained of deep-seated pains pretty generally distributed over the body, and enlarged glands were found situated in the neck, axillary and inguinal regions, beside the induration of the epitrochlears on either side. He also complained of troublesome headache. He was accordingly put upon mixed treatment for some time, without results. He had also suffered from eruptions upon the skin, and these, while observed in hospital, recurred at intervals, being

sometimes vesicular, sometimes pustular, sometimes in the form of large bullæ like those of pemphigus, which terminated frequently in superficial ulcers, and sometimes tubercular. These eruptions recurred from time to time, and then gradually faded out; they often occurred in the line of distribution of certain nerves, particularly those of the upper extremities, and, following the decline of the eruption, the affected region became anæsthetic, and so continued. About nine months before entering the hospital he noticed that the skin was becoming coarse and thickened over the eyebrows, nose, cheeks, and ears, with the characteristic appearance of elephantiasis. About two years since, after the unsuccessful employment of various remedies, he was put upon the use of chaulmoogra oil, and had repeated its use at intervals ever since, with great relief to his symptoms, particularly the pain and the formation of tubercular developments on the skin. He had taken as many as twenty drops two and three times daily. But ordinarily, after three or four weeks, the dose became so nauseous that he was obliged to discontinue it. Still his improvement had been very great. Aside from the deformities of the face, which had diminished, his chief source of complaint was the anæsthetic condition of his fingers, which made him bungling and clumsy in handling necessary objects, and in dressing himself.

AMERICAN LARYNGOLOGICAL ASSOCIATION.

The fifth annual congress was held at the hall of the Academy of Medicine, New York, on Monday, Tuesday, and Wednesday, May 21, 22, and 23, 1883. Dr. GEORGE M. LEFFERTS, of New York, President, in the chair.

After the roll of membership had been called by the secretary, Dr. D. Bryson Delavan, of New York, the address of welcome was delivered by the PRESIDENT, who referred to the full attendance at the present meeting, to the excellent work being done by the society, and to the best method of extending its membership, which was limited to fifty, and would be completed during the present session.

NEW FACTS IN LARYNGOLOGY.—The PRESIDENT read a paper with this title, in which he related the case of a young, strong, healthy man who, while sitting at the table, suddenly became unconscious, fell, and almost immediately arose and resumed the conversation. The attack had been repeated a number of times during the past eight years, and partial attacks occurred frequently. They were always preceded by a slight cough, the face became suffused, but no convulsive movements were apparent. Aside from slight hyperæmia, the laryngoscope revealed nothing abnormal. He had seen one other similar case. Charcot had given to the condition the term laryngeal vertigo; Gray, that of laryngeal epilepsy. Was there a relation, Dr. Lefferts asked, between the tickling in the throat with cough, and the fall and state of unconsciousness? He did not consider Charcot's views proved; were those of Gray correct?

Dr. LOUIS ELSBERG, of New York, regarded the attacks as due simply to a form of adductor spasm, while Dr. MAJOR, of Montreal, believed them to be a form of epilepsy, which view the President said he was disposed to accept.

A COMMON FORM OF VOCAL DISABILITY RESULTING FROM PATHOLOGICAL PROCESSES. THE PHENOMENA USED TO DEMONSTRATE THE FALSITY OF ONE SYSTEM OF VOICE TRAINING.—A paper with this title was read by Dr. S. W. LANGMAID, of Boston. The disability referred to consisted in an inability to sing above a certain note, or in a break in the voice at a certain point in the upward inflection, and occurred most frequently in the best singers and actors, who were called upon to put forth their highest endeavors. In soprano and tenor voices it occurred at nine in the key of C; in contralto and bass voices, at seven in the scale. The cause consisted in fatigue of the vocal mus-

cles, with or without slight injection of the mucous membrane. When the note referred to was reached on the ascending scale, instead of progressive closure of the glottis, especially of the posterior portion, sudden relaxation took place. The treatment lay partly with the laryngologist, but principally with the teacher. Attempting to sing falsetto at a degree of the scale where the normal tone was called for should be avoided.

Dr. CARL SEILER, of Philadelphia, had found that in the majority of cases the break in the voice was due to an enlargement of the pharyngeal tonsil, and a consequent narrowing of the resonance space, the correction of which resulted in a cure. There might also be relaxation of the vocal cords.

Dr. DALY, of Pittsburg, thought that general nerve stimulants, among which he mentioned ergot and nux vomica, should prove of benefit in connection with rest.

(To be concluded.)

Reports on the Progress of Medicine.

QUARTERLY REPORT ON GENERAL MEDICINE.

No. XIV.

BY ALEXANDER DUANE, M.D.

THE TUBERCLE BACILLUS AND PHTHISIS.—In an able lecture on the ætiological, diagnostic, and therapeutic relations existing between tuberculosis and its bacillus (*"Brit. Med. Jour.,"* Feb. 3, 1883), Dr. T. H. Green decides that the conditions necessary for the generation of the disease are found, first, in the presence of bacilli; second, in a hereditary or acquired predisposition which favors the occurrence of congestive and inflammatory changes in the lungs, particularly in the apical region where the circulation is retarded. The co-existence of these two factors seems to be essential to the production of true pulmonary phthisis. Accordingly, the therapeutics of the disease must regard both of these factors, and hence the indications for a rational treatment are, first, to promote the general health, improve the condition of the blood and of the vessels, and exercise the respiratory function, in order to prevent apical stagnation and inflammation; second, to prevent the access of the bacilli, or destroy them by antiseptic appliances when they have already effected an entrance.

THE DIAGNOSTIC VALUE OF THE TUBERCLE BACILLUS.—In the same journal for February 17th Dr. J. Dreschfeld, as the result of a large number of examinations, comes to the conclusion that bacilli are present (a) in all cases of fully developed phthisis, and (b) in cases which are still in the earliest stages and exhibit no physical signs. Further, (c) they are absent in non-phthisical chronic pulmonary affections (bronchiectasis, emphysema, fibroid pneumonia, anthracosis, catarrhal pneumonia, and syphilitic disease of the lungs). Lastly, (d) the author holds that the quantity of bacilli bears no relation to the intensity of the morbid process, and hence has no prognostic value. The results of Balmer and Fränkel, D'Espine, Heron, and Lichtheim are in the main concordant with those of the author, although several differ with him in regard to the prognostic importance to be attached to the presence of the bacilli in large numbers.

ANGINA PECTORIS AND THE THEORY OF COUNTER-IRRITATION.—In Dr. W. A. Sturge's article upon the phenomena of angina pectoris (*"Brain,"* v. 4, 1883) he explains the pectoral pain as well as the associated symptoms of dyspnoea, gastric disturbance, brachial soreness, etc., by the conversion of an efferent impulse conveyed along certain nerve-trunks (the cardiac

nerves) into a general commotion of the group of spinal nerve centers with which these trunks are connected, and by the consequent involvement of other trunks springing from the same centers. In this way disturbances arising in a deeply seated organ may make themselves apparent in the neighboring external parts. A similar process, but in the reverse sense, takes place when inflammation of a deeply seated part occurs from chilling or irritation of the superficial regions, and the efficacy of counter-irritation in relieving visceral pain is regarded by the author as an instance of the same law of diffusion. In the latter case he believes that we relieve pain by exhausting the sensitiveness of the center, which supplies nervous force both to the viscus and the overlying integument, so that by exerting a powerful impression upon the latter we inhibit the irritative action of the center upon the former.

CHANGES IN THE RENAL GLANDS IN BRIGHT'S DISEASE.—In the *"British Medical Journal"* for January 13, 1883, Dr. R. Saundby fully confirms the results obtained by Da Costa and Longstreth in relation to the co-existence of changes in the semilunar ganglia with inflammatory lesions of the kidneys. These changes are: 1. In acute Bright's disease, a simple increase in the round-cell elements of the stroma of the ganglia. 2. In the "large white kidney," a marked increase in the stroma as well as in the cell-elements. 3. In the mixed forms of renal inflammation, in addition to the changes above indicated, the ganglionic cells show signs of pigmentary degeneration, and the vessels may be dilated and hypertrophied. 4. In the atrophic kidney, the stroma of the ganglia is greatly increased in amount, the cell-elements are diminished, the ganglionic cells are scanty, shrunken, and in a stage of pigmentary degeneration, and the vessels are invariably dilated and hypertrophied. The number of cases examined by Saundby and the authors referred to was twenty-four, and in every one changes of the character just described were found in the semilunar ganglia. The constancy of this association of lesions seems to suggest a relation existing between the changes in the ganglia and those in the kidney; and Da Costa and Longstreth suppose that the latter may be the direct result of the former. Saundby, however, combats this idea and holds that the ganglionic lesions are the results of irritative action set up by the renal disease, it being well known that, in a great number of pathological conditions in which there is structural alteration of any of the viscera, irritative changes do occur in the related sympathetic ganglia.

Letters to the Editor.

THE INTERESTS OF HUMANITY AND THE OLD CODE.

NEW YORK, May 19, 1883.

To the Editor of the New York Medical Journal:

SIR: A constant reader of your valuable journal, I have been much interested in the articles which have appeared in its columns bearing upon the "Code Question," *pro* and *con*, and as I am not a member of either State or county society, or of the American Medical Association, and consequently unfettered in the matter of "Ethics and Etiquette," except in so far as every man is bound by that *unwritten code* in his intercourse with his fellowmen, I feel that I can view both sides of the question with a freedom of thought which is apparently impossible to either of the opposing factions.

As I understand the question, the entire controversy hinges on the consultation clause, which under the new code "*permits*"—not compels, nor even advises—simply permits a regular physician, in the exercise of his own judgment and in the interests of humanity, to consult with any legally qualified practitioner of whatever school or belief. It

does not seem probable to me that a regular would seek such a consultation, nor ought it to be possible that he would refuse it when solicited, if demanded by the interests of humanity—that is, if, in his opinion or in the opinion of the physician requesting his services, there was the shadow of a chance of saving the life of an individual. And I think I am right in presuming that under such circumstances only would such a consultation be requested.

It seems quite as inhuman under those conditions for a "regular" to withhold his advice and skill as it would for an orthodox minister to refuse to pray for a dying Unitarian—and what would be said of a minister who did so refuse? Perhaps a case in point will illustrate the—shall I call it—barbarity of such a refusal. In a neighboring city some few years since a gentleman was thrown from his carriage, and conveyed to his home in an insensible condition. The family physician, a man of education, a gentleman in every sense of the word, but a homœopath, was hastily summoned. After vainly employing all the resources at his command in attempts to restore the patient to consciousness, with a full realization of the gravity of the case and of the necessity for prompt and active measures, he said to the family: "I must have immediate surgical assistance; send for Dr. —; I think he is the only physician in the city who can render any real service." A messenger was immediately dispatched for Dr. —, to whom the urgency of the case was stated, "Who has charge of the case?" "Dr. A." "He is a homœopath; I can not attend the case unless he is discharged." "But Dr. A. is the family physician, and it was at his request that you were sent for, because he thought that your skill might be the means of saving Mr. —'s life." "I am sorry for Mr. —, but I can not go." The patient died. Now, Mr. Editor, if that is the ethics and etiquette, the *humanity* of the old code, the sooner the new code is adopted by every medical society in the country, the sooner will the public receive from the medical profession that which is its just due.

"LIBERTY."

Miscellany.

DR. JOHN C. MINOR ON "SECTARIAN FELLOWSHIP."—Dr. Minor, one of several gentlemen who recently withdrew from the Homœopathic Medical Society of the County of New York, writes as follows in the May number of the "New York Medical Times":

"In responding to a request that I should contribute something on the subject of sectarian fellowship to this journal, I assume that, since the request follows so closely after my resignation from all homœopathic societies, it is to be considered as an invitation to define my position with reference to homœopathy rather than to attempt an analysis of the system. As one of its former editors, there is no more appropriate place for the expression of my opinions than is afforded through this medium, and I feel that, under the present circumstances, no apology is needed for giving expression to my views in the personal form.

"While I am conscious of being in accord with many, it would be assuming too much to attach any other importance to the views I may advance than pertains to an individual opinion. I speak for myself alone, and have no fault to find with those who hold to different opinions. I may state in the outset that my resignation from the homœopathic societies is not due to any change in my estimate of the value of homœopathy. I have nothing to recant or retract, nor have I any grievance to ventilate. My action is based on the ground that a society that is distinctly sectarian in origin, character, and name, can not be accepted as the proper representative of any others than those whose belief is in harmony with this threefold characteristic. Such a society may tolerate the presence and welcome the assistance of those who reject the doctrines that constitute the system of homœopathy; it may allow the largest practical liberty of opinion to those who deny that the homœopathic law of cure is infallible or universal; it may receive into membership those who refuse to follow an exclusive system of practice, or to accept the appellation of 'homœopath'—all this is creditable to the liberal spirit of its members;

but, nevertheless, in its representative capacity, the society has not and can not have any other than a purely sectarian character.

"*Bliving, as I do, that the formula SIMILIA SIMILIBUS CURANTUR forms the best general guide in the selection of remedies, I do not recognize it as a law nor follow it as an exclusive method, but exercise the right belonging to every educated physician to make practical use of any established principle in medical science, and to employ any facts in therapeutics that are founded on experiments and confirmed by experience, so far as in my judgment they may tend to promote the welfare of those under my professional care.*

"The members of the Homœopathic Medical Society of this county will recognize this statement as essentially the resolution which, as chairman of a committee, I submitted to the society in 1878, and which the society adopted, and afterward expunged from the record 'as unconstitutional, null, and void.'

"I think the society was right, for, while it would have been in accord with my wishes, and with those of the supporters of that resolution, for the society to have taken its stand as an unsectarian organization, such an attitude would not have been fairly representative of its members as a whole, nor would it have been in harmony with its distinctly sectarian name and purpose. The resolution was too radical for the time. Had it prevailed, the next step must have been to drop the homœopathic name. Although the society distinctly refused to recognize the right of educated physicians to use any other principle in medicine than that of homœopathy, it must be conceded that its refusal was consistent; it was consistent in its adherence to homœopathy as the only law of cure, and to the homœopathic formula as an infallible guide; but, as this position is radically opposed to my own views, the society can no longer be my representative in medical politics without a sacrifice of consistency on my part that I am not prepared to make, and therefore I leave it to those whose views it represents.

"Much as I value the professional qualifications and ability of those in the old school, association with them is purchased at too high a price when it involves either a denial of what experience has taught me, or the acceptance of toleration instead of fellowship. As between the two schools I have nothing in common with the exclusive views of the one or the traditional prejudices of the other, for I can see but little practical difference between the dogma of assertion and the dogma of denial, when one lacks proof and the other lacks knowledge.

"For those who are not familiar with the past controversies of the two schools of medicine, it is natural to inquire what necessity existed for a physician, holding to no exclusive theory or practice of medicine, claiming the title of physician instead of any sectarian appellation, and exercising his own judgment as to the methods employed in his practice, to identify himself with a distinctly sectarian organization?

"To this I reply, and not for myself alone, that the necessity was created and the action compelled by the prejudice and intolerance of the old school. To consult with a homœopath was to be driven in disgrace from every society, and to forfeit all professional standing and fellowship. To investigate homœopathy impartially, and to acknowledge that it possessed any merits, was to incur the active hostility of every organization, and to invite public abuse and insult. So bitter and intense was this feeling that it permitted no consideration of private character or professional standing to interfere with its action, but was adopted as a settled and inflexible rule in all cases. So far as the professional standard of homœopathic physicians could be fixed by the old school, there were only two kinds recognized as possible—fools or knaves.

"Under such circumstances there were but two courses open to those who chose to be guided by their own judgment with reference to homœopathy—they could be forced out of the old school, or they could go of their own accord, but go they must. And this explains the fact that I, among others, preferred the association of those who, while professing an exclusive doctrine, permitted the utmost latitude of opinion and action, to the fellowship of others who, professing the utmost liberality, were governed by the laws of a trades-union.

"I should be untrue, however, to my personal knowledge of men and affairs in the profession if I failed to distinguish the fact that, while this policy of traditional prejudice and intolerance has been the

dominant party spirit in the old school, it is deprecated by many of its ablest members. And in the homœopathic societies there are those who, while using the principle *similia similibus curantur* as far as their experience confirms its value, are, nevertheless, physicians in the broadest sense, and are misrepresented by any sectarian appellation; so in the old school there are many whose spirit of liberality and sense of professional courtesy are misrepresented by the policy of their society organizations. There is a large class of men in the profession who, without exhibiting any particular bias for or against homœopathy, have expressed their regret that such a policy existed in their organization, believing it to be contrary to modern ideas of the broad and catholic nature of medical inquiry, and contrary to the fact that, in a science at once so uncertain and so progressive as medicine, it is neither necessary nor wise to establish a line of demarcation between orthodoxy and heresy. Such a policy would have been appropriate to a purely sectarian body; it would have been a logical outgrowth of a system that was promulgated as the only true, infallible, and universal method of cure, but it is a most glaring instance of inconsistency when liberty of opinion and action, as the rights of educated physicians, finds its supporters in a sectarian organization, and its enemies among the members of a liberal and unsectarian profession.

"This brings me finally to the ethical problem as it stands at present. That the present discussion of the code of ethics is in the nature of a rebellion against antiquated prejudices and a policy of intolerance, that it is founded on an assertion of the broad principle that liberty of opinion and action is the right of every educated physician, is evident to those who appreciate the issues involved. The question of consultations with homœopaths is a mere incident in the discussion, and should not be allowed to hide the broader principle upon which it rests. No matter what position is finally assumed on this question by the old school, one important feature is already developed in the practical assertion of a liberal sentiment, of an unprejudiced mind, and of professional courtesy as the characteristic of many who have hitherto been misrepresented by the policy of a dominant faction. Against such it will be impossible to bring the old charges of prejudice and intolerance, and hence a very important feature of all past controversies on the subject of homœopathy will be eliminated from future discussions. Homœopathy must depend in the future, not on the easy defense that is possible against indiscriminate assault, but upon the results of sober investigation at the hands of those who will examine its claims and test its merits with impartial minds, not in the spirit of destructive criticism, but with the honest purpose of getting at the truth. So far as I can judge of the general drift of professional opinion, the current is tending away from narrow channels and out into a broader expanse, where there is room for all that is honest in purpose or effort. I look for no millennium of harmony, for experience will differ and opinions will clash for ever, but I look for more rational methods of inquiry, for truer conceptions of professional rights, for less of cant and more of justice, as the natural outgrowth of a sentiment that is wide-spread in the profession, and is not confined to any school nor represented by any organization."

ANOTHER RESIGNATION FROM THE HOMŒOPATHIC COUNTY SOCIETY.—Dr. Henry B. Millard has resigned from the Homœopathic Medical Society of the County of New York.

GAILLARD'S MEDICAL JOURNAL ON THE CODE QUESTION.—Under the heading of "A Strange Inconsistency," "Gaillard's Medical Journal" for May 12th says: "The advocates of the new New York Code of Ethics say that they had not in view the profit and great money gain resulting from consultations with irregular physicians. They claim that they acted on grand, equitable, humanitarian convictions, and, so doing, that they challenge scrutiny and public criticism. And yet—and yet—at the mere threat of having their names published as a guide to those physicians who wish to send patients on to New York to such physicians as are in affiliation with the profession at large, these advocates of equity, humanitarianism (and the rest of it), are so alarmed that they fly to the New York 'Tribune' and to the 'Medical Record' for protection and defense! If these gentlemen have their own approval, of what are they afraid? Rather should they be glad to see their names given to the public as the names of those who are hyper-

equitable and extra-humanitarian in their relation to those who need professional assistance. And if, as a rational and natural result, the physicians of the entire country send their patients to New York physicians in affiliation with the profession, the advocates of a higher humanitarianism should be more than content to suffer for their sublimated principles. Like Othello, they should endure, they should with him cry: 'Tis the cause, my soul,' and be proud to suffer all things and endure all things, for justice and the right."

In the same number of the journal in question we find the list of signers of the declaration against the old code. Indeed, there does seem to be a little "inconsistency" in the matter.

TYPHOID FEVER AND INFECTED MILK.—There appears to be, in various parts of the country, a fresh crop of epidemics, due to the use of infected milk. Not long ago we had to speak of such an outbreak at Woborough; another—particulars of which are not yet available—is reported at Gateshead; and a third has just occurred at Exeter. The facts in each instance are of the familiar type. Cases of typhoid fever are discovered in houses which have no community of circumstances, except that they are supplied with milk from the same dairy. Inquiry reveals a case of disease at the dairy, or in its vicinity; the water-supply of the dairy is found to be from a source exposed to surface-soakage and excremental pollution; and there is usually also a suspicion that the water, though nominally used only to "cleanse the cans," has also been surreptitiously added to the milk itself. Dairies being for the most part situated outside municipal limits, this supervision becomes therefore the affair of the quarter sessions, and not that of the sanitary authority. Except in one or two cases, when the magistrates have had the sense to appoint the local officers of health as inspectors of dairies, it is hardly too much to say that the Orders of Council dealing with this matter are a dead letter. The health officer of Exeter, Dr. Woodman, in reporting to the Town Council the circumstances of the epidemic, suggests that "steps should be taken to have all dairies supplying a town periodically inspected and reported on." Evidently this is a first principle of effectual hygienic machinery, and it is little short of a national scandal that the present mockery of legislation as to regulation of dairies should be permitted to continue.—*Brit. Med. Journal*.

THE CHEMICAL LABORATORY OF THE JOHNS HOPKINS UNIVERSITY.—The President of the University is reported to have said recently: "While it is no doubt true that modern educational methods require large expenditure of money, it is also true that money may be wasted, and I think that some of the large laboratories furnish proof that money has been wasted. Regarded as a palace, our new laboratory is not, of course, to be compared with these, and I am glad of it. It is smaller, though plenty large. It is much less expensive in all its details, but—please note this particularly—it is not a whit less useful. It was built for use, and I think I can safely say that, when looked at from the standpoint of utility, it will bear the closest scrutiny. I believe it to be as good a laboratory for the teaching and advancing of chemistry as exists anywhere to-day, and it is superior to most."

THE LUNACY LAWS OF THE STATE OF NEW YORK.—A committee of the Medical Association of Central New York, consisting of Dr. Theodore Dimon, Dr. J. D. Button, and Dr. W. J. Heriman, appointed to report upon the advisability of changes in the New York lunacy laws, presented a long and carefully prepared report at the recent meeting of the association, concluding with a recommendation that the following resolution should be adopted:

Resolved, In the opinion of this Association, the lunacy laws of the State of New York have been carefully considered and wisely framed for the management and treatment of the insane, and it is not so much needed that these laws should be changed as that healthy public opinion should give its support to their successful administration.

COMPULSORY DRAINAGE OF VACANT LAND.—The Governor is reported to have signed a bill lately passed by the Legislature giving the Board of Health of the city power to compel the drainage of unimproved property within the limits of the city.

A MONUMENT TO FABRICIUS.—The municipality of Asquapendente asks co-operation from other Italian towns, and from public institu-

tions, in the establishment of a monument to the memory of Girolamo Fabrizio, surnamed "d'Acquapendente," more commonly known as Fabricius ab Acquapendente, the great anatomist to whom we owe our knowledge of the valves of the veins.

THE AMERICAN LARYNGOLOGICAL ASSOCIATION.—At the recent annual meeting, the following-named gentlemen were elected officers for the ensuing year: President, Dr. F. H. Bosworth, of New York; First Vice-President, Dr. S. W. Langmaid, of Boston; Second Vice-President, Dr. S. Johnston, of Baltimore; Secretary and Treasurer, Dr. D. B. Delavan, of New York; Librarian, Dr. T. R. French, of Brooklyn; Member of the Council, Dr. Beverley Robinson, of New York. Dr. C. W. Chamberlain, of Hartford, and Dr. J. N. Mackenzie, of Baltimore, were elected to resident fellowship. The next meeting will be held in New York, beginning on the third Monday in May, 1884.

THE MEDICAL ASSOCIATION OF CENTRAL NEW YORK.—At the annual meeting, held in Syracuse on the 15th inst., Dr. F. A. Mandeville read a paper on aphonia; Dr. W. S. Ely, of Rochester, reported a case of post-partum hematocele; Dr. C. S. Starr related a case of pyonephrosis; Dr. J. O. Roe read a paper on laryngeal sarcoma, and Dr. W. F. Sheehan read a paper on the differential diagnosis of variola and vari-cella. Dr. C. S. Starr was elected president; Dr. R. M. Moore a censor of Syracuse University; and Dr. W. F. Sheehan a delegate to the American Medical Association.

THE MASSACHUSETTS MEDICAL SOCIETY.—The one hundred and second annual meeting will be held at the Institute of Technology, Boston, on Tuesday and Wednesday, June 12th and 13th. The following order of exercises is announced: *Tuesday Morning.*—A paper on the tubercle bacillus, by H. C. Ernst, M. D., of Jamaica Plain; two papers on ergot, by G. L. Woods, M. D., of Springfield, and W. A. Dunn, M. D., of Boston. *Tuesday Afternoon.*—A paper on glycogen, by J. W. Warren, M. D., of Boston; one on phlyctenular disease of the eyes, by O. F. Wadsworth, M. D., of Boston; one on minor injuries of the spinal cord, by B. H. Hartwell, M. D., of Ayer; and one on plumbing appliances, by T. M. Clark, A. B. *Wednesday Morning.*—Business meeting; a paper on recent changes in the method of medical instruction, by E. N. Whittier, M. D., of Boston; one on neurasthenia, by J. S. Greene, M. D., of Dorchester; one on the artificial feeding of infants, by J. W. Spooner, M. D., of Hingham; one on the early symptoms of general paralysis of the insane, by W. B. Goldsmith, M. D., of Danvers; communications from the reporters of the district societies; introduction of delegates. At noon the annual discourse will be delivered by Dr. Amos H. Johnson, of Salem, and the annual dinner will take place at one o'clock, at the Skating Rink.

THE MEDICAL AND SURGICAL SOCIETY OF THE NEW YORK POLYCLINIC.—Under this title the faculty of the Polyclinic and the physicians who have attended the course of study at that institution have organized a society, the objects of which are: 1st. "To encourage the efforts being made in perfecting clinical teaching, and in the advancement of the standard of medical education." 2d. "To cultivate friendly personal relations between the practitioners who attend the Polyclinic with each other and with the faculty."

All physicians who hold a certificate of attendance at the Polyclinic are entitled to membership. At the time of organization the members numbered one hundred and fifty, exclusive of the faculty. The officers for the first year are: President, Dr. R. F. Blount, of Indiana, Chairman of the Section on Diseases of Children of the American Medical Association; Vice-Presidents, Dr. C. C. Burke, of Texas, Dr. J. W. McDowell, of Iowa, and Dr. J. A. Wyeth, of New York; Permanent Secretary and Historian, Dr. E. A. Ayers, of New York.

THE MARINE HOSPITAL ON BEDLOE'S ISLAND.—The work of removing the patients to the Seamen's Retreat Hospital, Staten Island, was begun last week, preparatory to the surrender of Bedloe's Island to the work of laying the foundation of the Bartholdi Statue of Liberty.

PROFESSOR CHANDLER AND THE BOARD OF ALDERMEN.—A petition having been transmitted to the Aldermen by the Mayor, expressing the desire of several thousand citizens that the board should reconsider its

adverse action on his nomination to another term of service on the Board of Health, the Aldermen returned the petition to the Mayor with an expression of opinion to the effect that they had no right to reconsider their action.

THE ALDERMEN AND THE CONTAGIOUS DISEASES HOSPITAL.—Last week the Board of Aldermen passed a resolution protesting against the establishment of the Board of Health's proposed hospital in Sixteenth Street for children suffering from infectious diseases. With regard to the real interests of the tenement-house population, the Aldermen could not have taken a more stupid course.

THE NEW YORK EYE AND EAR INFIRMARY.—Dr. Adolph Rupp, formerly an assistant surgeon, has been appointed one of the aural surgeons to the infirmary.

THE STATE BOARD OF HEALTH.—Dr. G. M. Moore, of Rochester, and Dr. Elisha Harris, of New York, have been re-elected president and secretary of the board.

GLANDERS IN ILLINOIS.—The "Weekly Medical Review" says that glanders has appeared among the horses of Whiteside and Perry counties in Illinois, and two persons, a father and son, have died, having become inoculated with the poison while caring for their sick horses. Strict measures are said to have been taken by the authorities to prevent a spread of the disease, a number of the animals having been shot and others quarantined, and it is believed that the disease is now entirely under control.

THE PROTECTION OF VICKSBURG AGAINST YELLOW FEVER.—The Health Officer of Vicksburg, Miss., has addressed the following petition to the secretary of the National Board of Health: "Having learned that the inspection service on the Mississippi River will be put in operation at Memphis, we would respectfully request that all inspection stations be established below this city as soon as possible, to be governed and managed as heretofore. This request is made for the reason that yellow fever prevails in several of the tropical ports, and we wish to be protected as far as possible by such inspection."

DEATH OF DR. JOHN D. BRUNS, OF NEW ORLEANS.—Dr. John Dickson Bruns, a prominent physician of New Orleans, died in that city on the 20th inst. Dr. Bruns was a native of Charleston, S. C., and received his medical education at the South Carolina Medical College. During the late civil war he served in the medical corps of the Confederate army, and afterward settled in New Orleans, where he held several professorships at different times, and achieved distinction as a lecturer.

DEATH OF MR. RICHARDSON, OF DUBLIN.—Benjamin Wills Richardson, F. R. C. S. I., etc., the well-known Dublin surgeon, died April 29th, at the age of sixty-four years.

DEATH OF M. MARTIN-DAMOURETTE.—The "Gazette hebdomadaire de médecine et de chirurgie" announces the death of M. Martin-Damourette on the 22d of April, at the age of sixty-one years, and adds that, although never enjoying an official position, the deceased gentleman was an accomplished private teacher of therapeutics to whom more than ten generations of his pupils are indebted for the better part of their knowledge of that branch of medicine.

NAVAL INTELLIGENCE.—List of Changes in the Medical Corps of the Navy during the week ending May 19, 1883.—Surgeon William A. Corwin, detached from the receiving ship Colorado and granted sick leave for three months. — Passed Assistant Surgeon M. H. Crawford, detached from the United States steamer Pinta, and ordered to the Navy-yard, League Island, Pa.

SOCIETY MEETINGS FOR THE COMING WEEK.—Monday, May 28th: Medical Society of the County of New York. Wednesday, May 30th: Arkansas State Medical Society (Little Rock.—First day); New York Medico-Legal Society. Thursday, May 31st: American Surgical Association (Cincinnati.—First day); Arkansas State Medical Society (second day). Friday, June 1st: Practitioners' Society (private); American Surgical Association (second day). Saturday, June 2d: American Surgical Association (third day).

Original Communications.

THE STATUS OF THE MEDICAL PROFESSION IN THE STATE OF NEW YORK.

By HENRY G. PIFFARD, M. D.

Fifth Article.

AFTER the committee had agreed as to the report that should be made to the society, it directed that it should be printed in advance of the meeting, in order that it might be placed in the hands of those present at the earliest possible moment after its reception by the society. This was done that each and every member might have an opportunity to carefully consider its contents and prepare himself to offer objections to it if he saw fit to do so. The report was printed with the lines numbered, to facilitate reference when it came under discussion. It was presented at the morning session of February 6, 1883. It was duly received, the printed copies were distributed to the members, and the subject was made the special order for the evening session. During the day, and up to the time of its formal consideration, the code was the chief subject of conversation, and it is safe to say that it was looked on by the members from all sections of the State as a very decided improvement on the American code, and one that, in its practical operations, would accomplish much good for the profession in the State. The members present were apparently almost unanimous in its favor, the leading comment being that the change was one that should have been made years before.

At the evening session, the report of the committee having been read, Dr. Agnew moved that it be discussed *seriatim*. Dr. Roosa moved, as an amendment, that it be discussed as a whole, which was ordered. Dr. Roosa, taking the floor, then said:*

If the society will bear with me in a few remarks, I will at their close offer a substitute for this report. I recognize the character of the gentlemen who have made this report. Without exception, they are the honored servants of this society; without exception, they have had peculiar opportunities to learn the will of the profession in this State with regard to the code of ethics. I also recognize, Mr. President, the very great difficulty under which this distinguished committee has labored, for I remember that behind them are the traditions of a profession that believed it was necessary to bind each other with very strong legal bonds in order to prevent harm. I remember that they saw the traditions which were thought to be as obligatory as those of the Mosaic code, and necessary in order to promote righteousness among medical men. I therefore see their difficulties, and I honor the result of their labors. I believe that it presents a great advance over anything which has been offered to our profession up to this time. But my objection to this report is that it contains nearly every one of those things which in the progress of time have become distasteful to the profession of our day. I believe that it contains in it the very intrinsic objections which we constantly make against the code which I hold in my hands—this sentimental code of our forefathers,

which tells us how our patients should behave toward us, and which enters into such innumerable details as to the relations we sustain to our fellow-men that it is impossible to believe that the authors of it thought the medical profession was entitled to any discretion in the management of its own professional affairs. I think that if the committee had fully studied the sentiment of the profession of the Empire State they would have wiped out the code of ethics from its beginning to its end. I believe they would have left such matters to be settled by the individual discretion and wisdom and the good faith of each man in affiliation with this society.

After further remarks, Dr. Roosa offered the following substitute for the report of the committee:

The Medical Society of the State of New York, in view of the apparent sentiment of the profession connected with it, hereby adopt the following declaration, to take the place of the formal code of ethics, which has up to this time been the standard of the profession in this State.

With no idea of lowering, in any manner, the standard of right and honor in the relations of physicians to the public and to each other, but, on the contrary, in the belief that a larger amount of discretion and liberty in individual action, and the abolition of detailed and specific rules, will elevate the ethics of the profession, the medical profession of the State of New York, as here represented, hereby resolve and declare that the only ethical offenses for which they claim and promise to exercise the right of discipline are those comprehended under the commission of acts unworthy a physician and a gentleman.

Resolved, also, That we enjoin the county societies, and other organizations in affiliation with us, that they strictly enforce the requirements of this code.

Dr. H. G. Piffard, of New York, moved that the substitute be referred to the Standing Committee on Ethics, to be reported upon next year. The motion was lost.

Dr. Squire, of Elmira, then spoke to the subject, and was followed by Dr. Van der Poel, who said:

Let us for a moment see where we stand. The special committee upon the code of ethics, after consultation, have presented this report for adoption. That report is objected to upon the one hand by Dr. Roosa, because, liberal as we have made it, it does not go as far as he thinks it should, and we have placed restrictions upon ourselves which Dr. Roosa wishes to have swept away. On the other hand, Dr. Squire thinks that we have swept away too much of our restrictions in some directions, and that we have not swept enough away in others. Now, let me state what was the spirit which governed us in making up this code as presented in this report. We reached the conclusion that it would be impossible to affect the relations of man to man, or the gentlemanly conduct and behavior between man and man. We can not make a man a gentleman unless he is made so by nature; it is utterly impossible to bind men in these relations by any code of medical ethics. For that reason we left these things out of our report. Every one of Dr. Squire's references relate to conduct between man and man, and, as we believe that no written restrictions can affect the moral character of the man, we simply say that, in our opinion, we should govern our conduct in consultations as we have indicated in the report. Dr. Roosa goes further than we do, and he wishes to restrict the medical profession only by those influences which are comprehended under the bonds "worthy of a physician and gentleman"; and says that it is utterly useless to make any obligation, and that it should be left to the moral de-

* The extracts from the discussions are taken from the official record as published in the *Transactions of the Society* for 1882.

cision of each practitioner, and if you choose to consult with any man, you are perfectly at liberty to do so. I think the time has come when consultation should be made vastly more liberal than it has been. I have grown up with all the prejudices and tendencies of a man educated at the time I was, and during my entire life-time I have not consulted directly or indirectly with a homœopath, and therefore I can speak without fear or favor. But, for a few years past, I have been somewhat removed from active practice, and I have looked over the question a little more dispassionately; and it has struck me, as well as others, that our position in this respect was painfully narrow and restricted. If we can break down those barriers and show up the homœopaths to the public, and break down the barrier which enables them to get sympathy from the public, and leave it openly with the conscience of every gentleman to go or not to go as he sees fit, I think it would be a very great advance. There are many physicians from the country here at this time, and doubtless they will support me in the statement that the instances are not few in which there are two physicians in a village—one a homœopath, and the other a regular physician, using the ordinary expression. The homœopathic physician, perhaps, has a severe case of sickness, and it becomes necessary to have consultation and advice, and the circumstances are such that he can not send away to get such consultation and advice. Now, it seems to me to be cruel and heathenish, although I have done it myself over and over again, to hang upon a miserable code of ethics and say I can not go. Such cases, I believe, should be left to the decision of the gentlemanly feeling and instinct of the man.

The present writer then took the floor and objected to Dr. Roosa's substitute, fearing that it would be generally interpreted as removing all restrictions on the conduct of medical men and lead to the most unbridled license, and, in fact, to an ethical status equivalent to that of the eclectics. These fears he now thinks were unfounded, but still very strongly objects to the "substitute" on grounds that will be stated later.

Dr. Frazier, of Camden, said:

Now, upon the one hand the laws of this State say that certain men are physicians, and make them so by law; and here we have simply an effort made to make our laws comply with those of the State of New York. By not doing so, we give to other physicians who do not belong to our school a very great advantage in permitting them to say, in different neighborhoods: "We are practicing according to the laws of the State of New York, but these men will not meet us in consultation according to the laws of the State under which we all practice." That has been the argument which they have used, and which makes them strong, and which makes us appear stubborn and weakens us. I have always been of opinion that we should be permitted to meet these men if the permission could be placed in proper language; that is, if we could be permitted to consult with them without making it obligatory that we should do so.

Dr. H. D. Noyes, of New York, said:

I have been looking for something which would explain to me what it was that gave rise to this system of rules which we know under the name of the code of ethics, but I have not heard whence it came. It seems to me it must have had a beginning in controversies and animosities and peculiar conditions, which have to a large extent, or, perhaps, entirely, been abolished. The present status of the medical profession is one in which there is a

high sense of personal dignity, and feelings of propriety among its members in their relations to the public and to each other. At the same time we all know that a considerable class of men—both those who are called regulars and those who are irregulars—are prone to do things improper and unworthy of gentlemen. Now, the code of ethics, as it stands, is doubtless intended to meet the latter class of men, but I think that our influence in controlling them is absolutely nugatory. I do not believe that the old code of ethics has amounted to anything in the way of restrictions upon them. Every physician can call to mind instances of flagrant violation of both the spirit and the letter of the code by men who have not been called to account. I do not think that the temper and the spirit of the substitute offered by Dr. Roosa are the temper and tone of such rules as are applicable to the present status of the medical profession. I will remember the feeling of surprise which came over me when the American Medical Association met in the city of New York in 1854, and I first read what is known as the code of medical ethics. I never was more struck with astonishment than with that document. It seemed to be saying things which were both humiliating and unnecessary, even at that time. I am sure that the sense of this meeting is for the abolition of that code as it now stands. . . .

. . . My feeling throughout my professional life has been, first, to study what my duty is to humanity, and, second, to consider what my duty is to the profession. It has been with me a strong desire, and continues now, to see wherein professional honor and propriety can be sustained, and, in deciding with reference to consultations, I must say that I have uniformly refused to consult with so-called irregulars. At the same time I have done so under the feeling that I was entitled to protest against it. I shall vote in favor of the substitute.

Dr. E. M. Moore, of Rochester, said:

I have had the same wonder which Dr. Noyes has expressed as to where such a code as theirs (American Medical Association code) could have come from, and I took pains at one time to investigate in that direction as to how we could have had such a wonderful composition. It was really copied almost verbatim from a treatise written by Dr. Samuel Percival in 1760, in accordance with the condition of society presented in England at that time, which was entirely aristocratic, governed by the law which regulates the relations existing between patron and client.

About seven or eight years ago this subject came up in the American Medical Association. It began to be doubted whether it was all right. I received at that time a letter from Dr. N. S. Davis, of Chicago, the father of the association, to whom this matter had been referred, and I gave him my views upon the question, calling attention to the fact that Dr. Percival wrote the article over a century ago, and expressed the opinion that we had entirely outgrown such swaddling clothes. At the next meeting of the American Association the committee brought in their report, and it was to the effect that the code of ethics was so excellent that it should be maintained. . . . I am willing to strike it all out and leave the regulation of our conduct to the unwritten law, for we have uniformly failed to apply the rules of discipline under any code or system of ethics by which we have been governed. . . .

Additional remarks were made by Drs. Mosher, Wight, Squibb, and Gray. It is a curious fact that not a single speaker defended the propriety of the consultation clause of the old code, or attempted to advocate the merits of this instrument as a whole. Many, however, thought it would be better to defer the decision of the question until after it had

been brought to the notice of the American Medical Association. The majority thought otherwise, and the vote showed 52 in favor of immediate action to 18 opposed. Immediately after the vote, Dr. Roosa gave notice that at the meeting in 1883 he would move the adoption of his "substitute."

On the writer's return to the city, the almost universal expression of opinion was in favor of the action of the State society, the adverse criticisms being very few in number. On the day of his return he was met in the street by a well-known physician, who asked concerning the ethical situation. On being informed, he said: "I suppose, then, I can call in a homœopath if I want to." I replied that I saw no reason why the rule didn't work both ways, but inquired why he wanted a homœopath. He replied that he had a very severe case of scarlet fever under his care, and that the family were very anxious, and desired a homœopath in consultation; and added that in all probability, if he did not have the homœopath, the family would discharge him and employ the other. He stated that, rather than lose the family, he would have the consultation, provided he could not be disciplined therefor. This gentleman is now enrolled as one of the supporters of the old code.

In the discussion of public affairs by the medical press, the same rules of order should prevail that are customary in deliberative assemblies. Language that is improper in the latter should find no place in the former.*

The publication of the action of the State society permitted the medical press throughout the country to criticise it, and this they did in a manner that was not altogether in harmony with that spirit of Christian charity that the old code was supposed to be founded on. If the falsehood, hatred, and malice displayed by some of the advocates of this code are to be regarded as its legitimate fruits, God forbid that it should ever again be the supreme medical law in this State. The change in the code was a matter that affected the profession of this State only, and was not the business or concern of any one outside the State. The State society, with perfect deliberation, and with its eyes open, resigned from the American Medical Association,† because it believed that the consultation rules of that body were both morally and politically wrong, and that further acquiescence in them would be to perpetuate the evils that had already accrued from their observance.

The medical press of the country, in dealing with the

action of the State society, with few exceptions, failed to discuss the question on its merits. Few, if any, sought to ascertain the real motives and reasons which rendered the change necessary or desirable; few even discussed the effect that the change would have on the affairs of the profession in this State. Few appeared to recognize the fact that it was the duty of the State society to watch over and protect the interests of the profession rather than to leave them to the tender mercies of the American Medical Association.

On the contrary, the majority of the press assumed to view the subject in a light which reflected most seriously on the intelligence or honesty of the profession in this State. One of the most prominent charges, and one which, after it had been first enunciated, passed current as truth from one journal to another, was the statement, wholly un-verifiable by facts, that this movement had been initiated and engineered solely by specialists from sordid motives.* The large vote (fifty-two to eighteen) by which the original change was made indicates either that the great majority of the profession in this State are specialists, or else that a very considerable number of general practitioners were of but one mind in this matter.

It may be asked why the State society did not first apply to the American Medical Association before taking this action on its own account. To which we may reply that, in the first place, it did not desire to carry a domestic affair into the councils of that body, to inflict its own views on the profession of other States, to make any attempt to proselyte in ground that was as yet unprepared, or to meddle with the affairs of those beyond its jurisdiction. Secondly, it knew the history of the American Medical Association too well to expect for a moment that it would listen to any propositions looking toward the liberalization of the profession. Almost from the beginning of the history of that association, its practical management and the dictation of its policy have been in the hands of one man—one who is commonly spoken of as the "Father of the Association," and who, so long as he retains his power, will continue to use it, as he has used it in the past, as an obstacle to the scientific and political advancement of the profession and the welfare of the people. For evidence on this point, we need but to cite the latest ethical ordinance adopted by that body—one which clearly showed the animus of the controlling element of the association, and exhibited its ever-readiness to meddle with the domestic affairs of the individual States. We refer to the action that was recently taken in

* As many are apparently unfamiliar with the proper limits of debate, and with the restrictions as to language that custom has thrown around it, I will quote from a recognized authority: "Another rule in speaking is, that no member is at liberty to digress from the matter of the question, to fall upon the person of another, and to speak reviling, nipping, or unmanly words of or to him. The nature or consequences of a measure may be reprobated in strong terms, but to arraign the motives of those who advocate it is a personality, and against order."—"Cushing's Manual," Rule 211.

† The severance of this connection was exactly similar in principle to that which occurs when a member, for reasons that seem satisfactory to him, severs his connection from a medical society by resignation. It is neither an act of secession, nor an act of rebellion, terms which have been used in this connection by those who should have known better.

* All of the New York specialists who had anything whatever to do with the matter, or voted on the question, were members of the New York Academy of Medicine, which was under the governance of the American code. The action of the State society in no wise affected the ethical status of that body, which is competent to adopt any by-laws that it chooses, or any code of ethics that it desires. These members of the State society, therefore, who voted for the change simply gave freedom to those who were not members of the Academy without releasing themselves in any manner from the Academy's code; nor have they, during the past eighteen months, made any effort, or organized any movement, to change the ethical status of the Academy. It will be seen, therefore, that the specialists were not governed by the sordid motives that have been ascribed to them. They, less than any one else, have been affected by the change.

reference to the University of Michigan. We regret that in Dr. Flint's recent articles on the code this ordinance escaped notice, as it appears to us to be utterly indefensible from whatever standpoint it may be regarded.

At home, the action of the State society was discussed more temperately. The two most important medical journals of this city approved the change, while one or two others of minor influence were opposed. The profession of the State as a whole gave the matter but limited consideration, but as a rule a favorable one; the old code was pretty generally regarded as dead, and the recent action was simply the interment of its remains. A few months later Dr. E. R. Squibb circulated throughout the profession of the State, in his personal organ, "*The Ephemeris*," a protest and an argument against the change. This action was the first incitement to dissension and trouble in the State, and we can not but regard it as ill-judged and in bad taste. Dr. Squibb is not a practitioner of medicine, and has not for many years been placed in a position that would enable him to have a practical knowledge of the questions at issue; and even if he had, he should have left the discussion to those whom it immediately concerns. As a recognized member of the profession, however, he had a perfect right, of course, to discuss the matter; but it would have been better, we think, if he had done so in one of the public medical journals, in which his views and opinions might have received reply. As it was, he of necessity had the entire argument to himself, and was enabled to give his personal views the widest distribution that he chose.

A journal in a neighboring city, with even less motive, endeavored to excite dissension among the members of the county societies in this State, and it incited them to seditious action, urging them not to accept the edict of the State society, but to adhere to the American code, apparently unaware that such action by the county societies would be absolutely null and void.*

Our Southern friends also, with great unanimity, censured the profession of the State, and even suggested that the malcontents form a new State society, forgetting the old rule in physics that two bodies can not occupy the same space at the same time. The distance which separated them from us and the different conditions which surrounded them are sufficient reasons for a misapprehension on their part of the propriety and necessity of our action. We think, however, that they might have been a little more charitable in the expression of their views. They frankly charged us with desiring to affiliate with the lowest quacks

and charlatans, just as in the old antebellum days they charged every abolitionist and opponent of slavery with the desire to marry his daughter to a "nigger." Long accustomed as they were to the idea that slavery of the body was right and proper, it may take them some years before they understand why it is that we in the North are unwilling to longer accept the slavery of the mind of which the old code represented the bonds.

Shortly after the meeting of the State society in 1882, an attempt was made to bring up the matter of the code in the New York Academy of Medicine. Notice was given that the action of the delegates from the Academy who had voted for the new code would be submitted to the Academy for its approval or the reverse. This was done by the friends of the old code who hoped to secure an expression of opinion adverse to the action of its delegates. At the meeting of the society at which the question was to be considered, Dr. Austin Flint, Sr., first claimed the floor, and, in a few brief but eloquent words, urged that the question be not brought up in that body, and moved that all action on it be indefinitely postponed, on the ground that the scientific interests of the association were too important to be hazarded by the introduction of medico-political questions of this character. This action was regarded by the opponents of the old code as almost a pledge that the question would not be raised again. They preferred to abide by rules and by-laws which were distasteful to them, and to gauge their conduct in accordance with ordinances regarded as oppressive rather than to risk the future harmony and welfare of the Academy. During the succeeding months the advocates of the State code rested on their oars, but the supporters of the American code were busily engaged in manufacturing opinion throughout the country adverse to the action of the State society. The most active agencies in this direction were the "*Medical News*" and the "*Ephemeris*," both of which endeavored to incite sedition in the county societies, urging them to repudiate the action of the State society, and to instruct their delegates to vote for the repeal of the State code.*

* The propriety of instructing delegates under circumstances such as these is open to question. It is not for a moment denied that the societies have the right to instruct if they so desire, but the wisdom of such a course is not equally apparent. Almost universal experience has shown that instructions are rarely given, except when a majority sees fit, through sheer force of numbers, to deny to the minority, no matter how strong it may be, any opportunity or share of representation. It is an expedient rarely adopted except when the majority fear that their cause is one that will not stand open discussion, and that their delegates can not be otherwise dragooned into its support. One of the most notable instances of this that occurs to us is a resolution that was adopted by the Philadelphia County Medical Society, April 23, 1879. About that time an almost universal cry had gone up to Congress to remove the oppressive duty from quinine. The medical profession were as a unit in the matter, except alone in Philadelphia. That city had for many years possessed the monopoly of the manufacture of this alkaloid, and feared that a removal of the aptly-called "blood-money tax" would injure its interests in this respect. From the swamps of the gulf-bordering States to those whose rivers flowed into the northern lakes there came a universal, heart-felt appeal for the removal of this onerous burden. Despite this fact, the physicians of Philadelphia, as represented in their county society, adopted the following:

* Any by-law or code of ethics that the county societies may see fit to formally adopt in opposition to the edict of the State society is absolutely without force, and contrary to the statutes of the State. It is not binding on the members, nor can it be enforced. The statutes of 1813 and 1866 give legal force to such by-laws only as receive the sanction of the State society; any others that may be adopted are of less value than the paper on which they are written or printed. The county societies may therefore, if they choose, cling to or adopt the American or any other code (not approved by the State society) for purely ornamental purposes. They may be assured, however, that such a code can not be of any other use to them, except, perhaps, to beguile the American Medical Association into admitting them to representation.

Thirty or more of the county societies followed this advice, and instructed their delegates to vote for the repeal of the State code. The societies that took this action were only those entitled to a limited number of delegates, and the aggregate vote thus obtained hardly counterbalanced the votes of two or three of the more populous counties. In none of the larger counties was this action taken. It is true that Kings County, entitled to twelve delegates, did at one meeting instruct its delegates, under the urging of Dr. Squibb, to vote for the repeal of the State code, but this action was rescinded at a subsequent meeting of the society.

In New York County, it being the year for the election of delegates, upward of forty nominations were made at the September meeting. Of these candidates I do not recollect the names of more than two or three who belonged to the old code party. From the forty nominees, twenty-four (the number prescribed by law) were to be selected. At the election in October, the entire number elected were men opposed to the old code. This was not in consequence of any special electioneering, as from the code standpoint it mattered little which of the forty (with two or three exceptions) were elected. Those elected owed their election to the fact that they were suitable persons for the position, and were sufficiently popular. One or two of the unsuccessful candidates were men equally suitable and personally popular, but their pronounced position in favor of the old code being known, they polled a very small vote.

After this, very little thought or attention was given to the code in this city, much less, in fact, than in other parts of the country, our neighbors appearing to be really more solicitous about our welfare than we were ourselves. Ethical matters slumbered, and it was not until the stated meeting of the county society in January, 1883, that the question was again opened. At this meeting, Dr. L. A. Sayre moved that the delegates of the society be instructed to vote for the repeal of the State code. After discussion, this motion was lost. Not satisfied with this expression of opinion on the part of the society, the old code advocates procured the calling of a special meeting for the announced purpose of obtaining a vote on the question. At this meeting the question of instructing the delegates was again raised, and a motion to that effect was lost by a vote of 60 years to 147 nays, the question having been discussed by Drs. Flint, Barker, Garrish, and others.

This brings us to the eve of the meeting of the State society in February, 1883. The history of that meeting and subsequent events will be considered in our next.

PROVISION FOR THE DESTRUCTION OF UNWHOLESOME FOOD.—The Board of Health of New York City has recently adopted such amendments to its sanitary code as to increase the authority of its officials to enforce the destruction of unwholesome food and adulterated milk wherever they may be found in the city.

"Resolved, That the delegation of this society to the American Medical Association be and is hereby instructed to use its best efforts to obtain the passage of a resolution requesting the Congress of the United States to make no change in the law regulating the duty on this valuable alkaloid or its salts."

These same physicians now demand that we shall pattern our morals and ethics after theirs.

THE CODE QUESTION.

By E. A. JUDSON, M. D.,

NEW YORK.

In attempting to follow the discussion of the code question, I have been embarrassed at times to keep clearly in view the practical issues involved. False premises have been so plausibly associated with maxims universally accepted as to elude ordinary vigilance, while premises sound in themselves have, by faulty process of reasoning, given the appearance of validity to weak conclusions.

Without attempting to discuss all the points raised on either side, I will briefly give what seem to be controlling facts in the case, with glimpses of considerations which have influenced the judgment of some in favor of upholding the national code until modified or abolished by the body in which it originated.

Until the abolition of this code by our State society, it was the recognized standard of medical ethics throughout the entire country. It was adopted by the American Medical Association in 1847 as a common bond of organic union, and whatever its defects may be in the opinions of some, and however far it may be departed from in the practice of individuals, there can be little doubt that the moral principles it inculcates and the spirit that animates it as a whole are calculated to elevate the tone of professional conduct, and establish at least tolerable conditions of fellowship for medical practitioners in all the States of our Union. The American Medical Association has raised the profession in our country from a heterogeneous mass of discordant elements into an organized body of intelligent men, recognizing paramount obligation to one central authority. The medical profession, in virtue of its peculiar relations to society, naturally commands attention to its recommendations to legislative bodies. Any recommendation is likely to meet with favor in proportion to the unanimity with which it is urged by the profession at large. In order to secure such unanimity we are obliged to give up local preferences to a certain extent, and to meet our professional brethren of other States on such common ground as we can find. This common ground must, of course, be the sentiment of the majority. At such meetings we are at liberty to advocate any action we may please, relying on the force of argument to convince those who may not be of our opinion. The effect of this method is perhaps slower than some may desire in a given case, but, if the action proposed is in itself desirable, the advantage of increased force and momentum will compensate for loss in rapidity, while, on the other hand, if we break up into separate and rival camps, we become more exposed to unfriendly attacks, and waste in bitter internal feuds the energy that might be more usefully spent in advancing common objects. The American Medical Association, composed of practitioners from all parts of the country, is more likely to judge wisely in matters affecting our relations to each other and to the public than State or county societies. Its annual meetings attract wider and more respectful attention both at home and abroad. The work of its sections is creditable, and yearly increasing in

interest and value. Its proceedings are conducted with a dignity suited to the noble objects of its deliberations, and marked by an ability fairly representative of the broad constituency for which it speaks. It is a purely voluntary association, and, so far, has not felt the need of any chartered rights or privileges. It assumes no authority over its members, except such authority as springs directly from the liberty of American citizens to associate together for lawful purposes, and prescribe the qualifications of their fellowship. Such as it is, its official utterances have now justly acquired a moral power and importance attaching to the utterances of no other organization of medical men in our country.

Now, it is an admitted principle, underlying all associations for whatever purpose, that each associate shall abide by the constitution and by-laws of the organized body. This principle, indeed, is essential to the very existence of the organization, for it is obvious that, if any associate may at pleasure alter or abolish such provisions of the constitution and by-laws as seem objectionable, there can be no common bond of union. When, therefore, our State society, without bringing the subject up in our National Association, or making any effort to change its code in the constitutional way, simply abolished it of its own volition, it was equivalent to withdrawal from the National Association. This action seems grossly discourteous to the American Medical Association, and a flagrant violation of sound principles of representative government and of general ethics. As a self-respecting body, the National Association could not consistently admit delegates from our State society after the action of the latter abolishing one of its by-laws. Strange as it may appear, some of the most conspicuous advocates of the action taken by our State society contend that we need no written code at all to define the courtesies of professional intercourse.

It may be admitted as a conceivable proposition, that a difference of opinion might arise between the American Medical Association on the one hand and the profession of a single State on the other hand, involving questions of principle of such magnitude as to warrant the latter in inflexible adherence to their views, even at the expense of surrendering the advantages of larger association. In that case, however, it would seem reasonable to expect that the disaffected State should exhaust constitutional means of remedy before resorting to the extreme measure of secession. We would also expect to find the profession of the seceding State practically united on the merits of the question, and agreed on the policy of maintaining their view at all hazards. All of these conditions are wanting in the actual case. The national code has been in operation for thirty-five years, and it can not be successfully argued that its abolition is a matter of such urgent importance as to warrant us in a total disregard for the opinions of our professional brethren in other States. It is well known, also, that the profession of our own State are far from united as to the wisdom of the changes proposed, while many who feel indifferent about the changes deem it unwise to adopt them in face of the earnest opposition of a large number, if not a decided majority, of the

profession in our State. However much we may prefer the State code to the national code, or no code to either, it seems far more desirable that we should have one code throughout the country, instead of forty; and one county society, and one State society, and one national society, instead of two rival societies in county, State, and nation. The latter condition is the logical tendency of the principle of action introduced by the advocates of the new code in our State society, and this seems enough to condemn their action, whatever may be thought of the merits of the different codes.

The national code was abolished by our State society at its annual meeting in February, 1882, by a vote of fifty-two to eighteen. It would appear, therefore, that this important question was decided, and the whole profession of our State committed to an attitude of hostility to the medical profession of the United States, by a voting body of seventy men. This action is now defended by some who participated in it, on the ground of regularity. They say that the subject of code revision had been regularly introduced and referred to a committee; that the meager representation on the occasion was due to the apathy of the profession; that they supposed, and had a right to suppose, this apathy a sign that the profession would readily acquiesce in the policy so regularly inaugurated and carried through. They profess to be much surprised at the earnest opposition and warm discussion now going on in local societies throughout the State. All this, so far as true, may relieve them of the just odium that would attach to the conduct of men who, acting in a trust capacity as representatives of important interests, should take advantage of the confidence reposed in them to intentionally misrepresent the sentiments and wishes of the body for whom they were acting. Now, however, it is evident that they were mistaken in so interpreting the apathy of the profession, and it would seem that the same sentiment of honor which leads them to repudiate any intention of wrong-doing should impel them not to insist on perpetuating the wrong, but to join those who are endeavoring to undo their work, so as to leave the question to be decided on its merits, as a new question, now for the first time being discussed with an interest adequate to its importance. Such, however, is not their attitude at present.

The effect of this apparent inconsistency is unfortunate, because introducing suspicion of motives and confusion of issues into a controversy which might otherwise be free from both.

The American Medical Association embraces in its scheme of organization the great bulk of the profession in the United States. It aims to elevate the standard of medical education, to promote uniformity of law regulating the practice of medicine and the dispensing of drugs in our various States, to afford favorable opportunity for comparison of experience, for discussion of scientific contributions, and for ascertaining and expressing the sentiment of the profession on matters of public interest affecting the health of the whole or any large section of the country. Whether we shall maintain this association, or act in a way calculated to break down its organization, seems to some a more important question than whether one code is intrinsically

preferable to another. To others, the latter question seems the more important.

The two sets of arguments obviously involve different sets of facts, and reach independent conclusions. Both questions, however, were opened at once by the recent action of our State society, and there is reason to believe that some worthy members of our faculty now find themselves in a false position, through incautiously weighing arguments not really antagonistic in opposite scales of the balance.

The idea has been advanced that, our State Legislature having recognized certain practitioners as legally qualified, we are in some way bound to permit consultations with them, and to modify our articles of association accordingly. This argument proceeds from the mistaken assumption that the Legislature intended to limit the right we have, in common with all other voluntary associations, to prescribe the terms of our fellowship. This right springs directly from that fundamental liberty which it is the pride of our institutions to secure. In exercising it, we violate neither the spirit nor the letter of the law. Not only is the assumption of the argument mistaken, but, even if correct, the ground taken would be equally untenable; for, if the Legislature of our State should, in any unguarded moment, seriously attempt to limit the freedom of a voluntary association to prescribe its conditions of membership, their action would be unconstitutional, and we should find ourselves in presence of an issue in comparison with which our code question would sink into insignificance. How men presumptively free from intellectual cataract or moral strabismus can elaborate this argument and persistently repeat it, as if themselves convinced, I leave for those to explain who make special study of nervous phenomena.

The principal argument urged against the national code is that it is illiberal and arbitrary in the matter of consultations, unduly curtailing individual liberty, and not sufficiently regarding the interests of the sick. The advocates of State codes and of no code ring the changes on this theme with infinite variations.

"Let us have freedom. Our fathers died for liberty. Away with old fogies, the fossil representatives of past ideas and generations, too long lingering in our midst, to retard the progress of our age with their antiquated notions of ethics, hundreds, nay, thousands of years behind the times! What do we want of ethics, anyway; we, the apostles of liberty and special champions of humanity in the midst of a bigoted and narrow-minded profession? Are we not honorable men and gentlemen? See what weighty characters we bear, and how we shine in the effulgent rays of noble distinction. History shows that persecution is profitable to the persecuted. We have the courage of our convictions, and are willing, even anxious, to wear the martyr's crown. And who are you who oppose us? You may have some physiologists among you, it is true, but what has physiology to do with practice? If you wish to enlarge the visual angle of your mind's eye, and develop your center of ethical sensibility, give exclusive attention to diseases of the eye, or ear, or skin, or female genital organs. Go to now, ye men of little weight, and make yourselves like unto us;

so shall ye be magnified in the sight of all the people, and your mouths shall be filled with fat things, yea, and your checks also shall in no wise be diminished.

Of course, I do not mean to say that all this is taken literally from the speeches or writings of those who defend the action of our State society, but that many of their arguments do seem to lean for support on the Jingo ideas conveyed in the foregoing words. There has been a great deal of beautiful talk addressed to the public, in order to create the impression that a battle is waging among the doctors, in which the friends of liberty and progress and everything that is lovely are on one side, and that the enemies of these excellent ideas are on the other side.

We know well enough that this is not the case, and that there is no question of civil liberty involved at all. The adherents of the national code, if they find themselves a majority in our State and district associations, propose to take possession of these organizations and control their policy. Should they succeed, those who wish freer consultations than may be allowed, or who consider the restrictions of the association in other respects too irksome to be borne, will be at perfect liberty to form such other associations as they please for mutual support and propaganda of their ethical views. Should the adherents of the national code find themselves in the minority, they will have the same liberty to form other associations, restricting their membership to such as are willing to unite on the terms proposed. Any bitterness of feeling and any injury to common interests that may result will be justly attributed to the peremptory action of those who, not content with their own secession from the main body of the profession in the United States, virtually insist that those who do not agree with them shall also sever their connection.

In the matter of consultations, it may be a fair question whether the attitude of the regular profession may not now be judiciously altered; but many of the arguments advanced in favor of the alterations proposed do not seem conclusive, and are founded on a misapprehension of what the attitude really is. Members of the regular profession hold themselves ever ready to relieve the suffering public, without any limitation in the choice of remedies or the mode of their administration, except the limitations imposed by an enlightened judgment and regard for the interests of the sick. Having investigated the complicated mechanism of the body, its various physiological and morbid conditions, and the means of relieving its maladies, they are strongly obligated to lead and not to follow public opinion in matters medical. Recognizing the responsibility of this leadership, and realizing, as the general public can not, the immense injury done to society by professors of the healing art whose pretensions are unscientific, and often fraudulent, the regular profession says to the public: "Our doors are always open. We welcome gladly all educated physicians into our midst, stipulating only the observance of such rules as may from time to time be adopted in order to secure the scientific standing and honorable character of the profession at large. We require subscription to no therapeutical dogma, because we can find no sound dogma of such general application as to make it a safe guide in

treating the various diseases and injuries to which we are called. We consider freedom from any such dogma essential, in order to secure the best results at the bedside of our patients. There is no good reason why any competent physician should remain outside of our ranks. If he does so, we do not care to meet him in consultation, for we are sure to disagree in our views, either of treatment or of the principles which ought to govern the conduct of honorable men, and disagreement at the bedside is unpleasant for all concerned, and, what is of more importance, dangerous to the patient."

If this is the real attitude of the profession, it may not be absolutely the wisest possible, but certainly does not deserve the harsh censure that has been so freely indulged in of late.

It is said that the code ought to be abolished because it has failed to accomplish its objects. In proof of this failure, we are pointed, on the one hand, to its infraction by those who are bound to observe it, and on the other to the continued existence, if not actual increase, of quackery. But infractions of the law and the continued existence of the evils sought to be remedied by it do not prove that the law ought to be abolished. Nor is it satisfactorily established that there is any more quackery at present than there has ever been. It is admitted that practitioners for whom special indulgence is now solicited have virtually abandoned their peculiar tenets, so that there is nothing to prevent their joining the regular profession, except the desire to reap pecuniary profit from erroneous notions, disseminated among the people, and still encouraged, though at heart despised, by themselves. I can not see how a normal moral sense can recognize these people as worthy of special approbation, or the fellowship of honorable men.

Quackery has flourished in all ages, and will continue to flourish so long as it is profitable. Medicine is only one field in the large domain of its enterprise. It adapts itself to all fashions and to all ranks and conditions of men. For the poor, and the ignorant, and the feeble intelligence, it has its faith cures, and clairvoyants, and seventh sons of seventh sons. For the rich, and educated, and superior intelligence, it takes a more reputable garb, borrows the language of science, assumes a Greek title, repeats a sonorous Latin formula, and talks learnedly of mysterious potencies and dynamized dilutions. These are the fashions of to-day. The form may change, but the thing itself remains the same. It flourishes on the ignorance and credulity of the public, and the richness of the soil was lately demonstrated, in a manner mortifying to the vanity of our age, in the Wiggins incident. Here was a veritable quack, if there ever was one, who succeeded, by sheer impudence, in foisting himself on the attention of the public. He pretended to be able to predict a terrible storm and immense tidal-wave by astrological calculations on the conjunction of planets. His previous predictions had signally failed to be verified, and yet, in spite of all this, many thousands of people had faith in his prophetic power, and regulated their movements accordingly. The effect was not confined to the ignorant; it included many of cultivated intelligence. The interest was so great that our leading metropolitan journals gave up several columns daily to the subject. Of course, there was no truth

whatever in his pretensions, but this seemed to make no difference. And yet we boast of our high civilization and wide diffusion of knowledge, with our steam-engine, and telegraph, and printing-press, and public school. An able writer in one of our newspapers, pointing the moral of this humiliating tale, remarks that "the amount of impression made by Wiggins's prediction on the public mind is, like spiritualism, a striking illustration of the small extent to which the masses are still influenced by what is called the scientific spirit."

Surely, in the light of such an incident as this, we may well cease to wonder when we hear of the marvelous cures wrought by charlatans of all kinds, and listen to the testimony of eye-witnesses who scoff at our incredulity. This state of things is due to the infirmity of our nature and to the imperfection of our knowledge, and will last until the principles of evidence are far more generally understood and appreciated than they are at present. Whatever the cause of the phenomenon may be, we must recognize the existence of a large class in the community to whom the awe-struck attitude of mind is congenial, if not habitual, and who are predisposed to contemplate with peculiar delight whatever is mysterious and marvelous. This class constitutes the Eldorado of quackery, whose rich mines, far from being exhausted to-day, are constantly alluring unscrupulous men into regions of questionable enterprise. Centuries of evolution have failed to eradicate the evil from society, and as physicians we must deal with it as a permanent factor. Is it best for the honor and character of our profession to abolish all moral considerations in formulating our tests of fellowship? Is it best for the interest of the public, to break down the barriers which, in spite of exceptions, do, to a certain extent, separate us from the horde of adventurers on the borders of medicine? Is it the dictate of humanity that the medical profession should deliberately encourage what it believes to be bad for the health of the community, and officially wink at errors and superstitions which, in all ages of the world, have impeded its progress?

As practicing physicians, we are drawn in one direction by our scientific relations and nobler impulses, and in an opposite direction by the baser claims of business expediency. "Temptation hath a music for all ears." Let us be careful not to imbue ourselves too deeply with ideas current in the commercial atmosphere that surrounds us. Let us uphold the banner of science, truth, and honesty. Let us leave therapeutical dogmas to our unworthy rivals, recognizing but one school of medicine—the acknowledged progressive school of rational medicine. Let us devote ourselves to the noble art of healing, receiving from the hands of science such ripened fruit as she may pluck from the tree of knowledge, and giving this to our patients, as the best that we can give them, so long as the tree of life shall remain inaccessible to human approach.

HYPERTROPHY OF THE BREASTS.—At the last meeting of the Société de Chirurgie, M. Desprès presented the portrait, painted by Horace Vernet, of a patient operated upon by M. Manec for hypertrophy of both breasts—the one weighing sixteen French pounds, and the other fifteen. The young girl who was the subject of the case afterward married and had four children.—*Mod. Times and Gazette.*

CONCERNING MEDICAL ETHICS.

By F. A. BURRELL, M. D.

"Let us have peace."

If the wisest men always gave us the best advice, to them might be referred the settlement of all doubtful questions; but experience teaches us that the choicest suggestions sometimes come from the simplest and most unexpected source. Even a stray bit of paper blown into our path by accident may contain the very item of information for which we had in vain ransacked the most promising authorities. So, it seems to me, any physician of the throng may, without explanation or apology, give publicity to his own views on this subject of medical ethics which has for several months occupied so much attention in medical circles.

The regular profession is at present divided into those who favor "the old code, the new code, no code, and an amended old code." Under these heads may be arranged the different shades of opinion which are connected with an agitation as general as any which has stirred the minds of physicians for years. It is very important that the question should reach an amicable solution, since men equally prominent and conscientious are arrayed on either side, and the opinions are held so decidedly that there is danger of another division in the profession. It is almost to utter a truism to assert that union is an element of strength both within the profession and in its relations to the public. Physicians are supposed by the public to be always differing from each other in matters of opinion, and a variance so great as that which now concerns the question of medical ethics would be regarded as only in keeping with the traditional discordance. Such a jarring undoubtedly lessens the respect in which physicians are held by the community, and the varied phases of the contest furnish choice newspaper items, where they are ranged with confessions from the scaffold and the exploits of the ring.

It is also desirable that a friendly settlement should be reached, since the number of those who are dissatisfied with the existing condition of medical ethics is very large. There is a feeling that the present regulations do not represent the necessities of the times, and it does not seem just to suppose that the discontent rests only upon a pecuniary basis. Many believe that under the code the virtuous are disciplined and have virtue for their reward, while the unscrupulous flourish unscathed. If only a small number of physicians were in the opposition, and these comparatively unknown, a large majority might demoralize or crush them. Perhaps this might be done even under the present circumstances. This, however, is doubtful, since the discontented represent the good qualities of the profession as well as their opponents; certainly among them are many who have always been esteemed and honored for their intellectual and social qualities. It is an opposition which should, if possible, be reconciled, and its strength saved for our general welfare.

Thus far there has been a contest in which old methods, sometimes reminding one of a political struggle, have not

been wanting. It is said that when men begin to differ in opinion they soon commence to call each other names. A moment's reflection will recall many epithets which have thus originated in the dissensions of the past. History is full of them, and collected together they would stock a vocabulary. So in the present instance we hear of "old" and "new codists," "old" (not new) "fogies," "the enemy," "quacks," and "trickery," as well as other terms. Such appellations do not imply that those who use them have lost all respect and esteem for their opponents, but they rather resemble the sparks which fly up from the furnace and indicate the intensity of feeling below.

One side summons its followers to be present at a meeting for the purpose of throwing an overwhelming vote in favor of some particular measure, and, when a similar course is pursued by the opposite side, the first are loud in their censure, and characterize the proceedings as worthy of a primary election. Even the force of law is suggested as a method of convincing those who are reluctant in the adoption of new measures. Thus the combat deepens, and all the time a settlement of the question is endangered by an ever widening breach. Physicians are men accustomed to a training which cultivates self-control and judgment, and it would seem as if some satisfactory basis of agreement might be attained from a calm consideration of what was best for the interests of the profession and the public, and what the times demanded. Such a conclusion would be more lasting and beneficial than any which could be secured by manipulation or machinery.

If we consider the old code of ethics, it stands before us as a historical document which has been a kind of rallying point for many years. It reflects the pure and lofty sentiments of its authors, perpetuates the fraternal relations of the medical profession, cultivates an *esprit de corps*, and breathes that philanthropic spirit without which medicine can not hold the high position to which, when worthily followed, it is eminently entitled. It can not be denied that its phraseology is antiquated; but through its quaint sentences appears that spirit of honor and integrity which medical men have always been taught to cherish and respect.

In so far as the old code refers to the duties of physicians to patients, and patients to physicians, this historical document would still have remained unchallenged, but there are two or three clauses which have elicited discussion, and chiefly that which refers to consultations. Here is the paragraph:

"ART. IV.—Of the Duties of Physicians in Regard to Consultations.

"SECTION 1. A regular medical education furnishes the only presumptive evidence of professional abilities and requirements, and ought to be the only acknowledged right of an individual to the exercise and honors of his profession. Nevertheless, as in consultations the good of the patient is the sole object in view, and this is often dependent on personal confidence, no intelligent regular practitioner, who has a license to practice from some medical board of known and acknowledged respectability, recognized by this asso-

ciation, and who is in good moral and professional standing in the place in which he resides, should be fastidiously excluded from fellowship, or his aid refused in consultation, when it is requested by the patient. *But no one can be considered as a regular practitioner or a fit associate in consultation* whose practice is based on an exclusive dogma, to the rejection of the accumulated experience of the profession and of the aids actually furnished by anatomy, physiology, pathology, and organic chemistry."

In the new code it is stated that "members of the Medical Society of the State of New York, and of the medical societies in affiliation therewith, may meet in consultation *legally qualified* practitioners of medicine. Emergencies may occur in which all restrictions should, in the judgment of the practitioner, yield to the demands of humanity."

The difference between the regulations of the new code and those of the old code in this matter is, that while in the one case the regular physician is allowed to meet any legally qualified practitioner, in the other case, if the physician in attendance belongs to the class of irregular practitioners, a regular physician may not meet him in consultation.

By the words of the old code, "in consultations the good of the patient is the sole object in view." But as a patient might, from loyalty to his attending physician—who, although of irregular proclivities, was a friend, or had, perhaps, aided him in previous illnesses—be unwilling to set him aside, or, in fact, unable, from domestic or other reasons, to do so, he would be obliged to forego the desired opinion. Thus the path to the bedside would be obstructed, and the statement which claims that "the good of the patient is the sole object in view" is not entirely correct. It would, I think, be more in accordance with facts to say that, regular physicians being in attendance, the good of the patient is the chief object in view.

There is also another clause in the old code which seems somewhat inconsistent, and this states that it is derogatory to professional character for a physician to hold a patent for any surgical instrument, which it ranks with a secret nostrum. To class the result of an original effort of the brain, in which are involved important scientific principles and which reflects credit upon an original and inventive mind, with some, perhaps, useless mixture of inert fluids or harmful compound which may even produce deleterious effects when ignorantly used, seems unjust and illogical. The construction of such instruments is no secret, nor do they in any way partake of the nature of a nostrum. Books are written, and sometimes it may almost be said that the name of the author is the only original sentence which they contain. These are copyrighted or patented, and the author receives his royalty on the sale. Where is the distinction which can be made to favor a book without originality, as against some useful mechanical appliance which combines the most scientific principles, and which would aid physicians vastly in their care of the sick? The spirit which prompted this clause seems eminently worthy of its originators. It was intended that no restrictions should be placed upon any means which might benefit the community. Practically, however, things were brought together which

are essentially different, and, as it were, have been disposed of in one lot.

These two clauses, with the exception of one other, which refers to methods sometimes resorted to for the purpose of obtaining notoriety, are the only ones concerning which there has been any difference of opinion among the mass of physicians. The instructions which the time-honored document gives are those of a sound *vade mecum*, and might be occasionally consulted by all of us with benefit, as indicating the lofty aims of professional life.

The clause referring to unusual methods of obtaining notoriety is here subjoined:

"It is derogatory to the dignity of the profession to resort to public advertisements, or private cards, or handbills, inviting the attention of individuals affected with particular diseases, publicly offering advice and medicine to the poor gratis, or promising radical cures; or to publish cases and operations in the daily prints, or suffer such publications to be made; to invite laymen to be present at operations, to boast of cures and remedies, to adduce certificates of skill and success, or to perform any other similar acts. These are the ordinary practices of empirics, and are highly reprehensible in a regular physician."

Against such gross methods of obtaining prominence the general sentiment of physicians is firmly set. Still it must be admitted that under the pressure of the increased competition of the present day the deference which is paid to wealth, and the observation that bare notoriety is an ample *πῶς ὄρω* for the display of professional abilities, the privileges of advertisement are strained to the extreme limits of the ethical tether. A glance at current medical literature shows a latent desire that, if possible, there should be an equalization of rights in this respect, or, to use a common phrase, no handicapping. An honored authority in ethics, as in medicine, thus writes of this section of the code:

"There can be no difference of opinion in the minds of worthy physicians as to the acts which in the third section of this article are specified as derogatory to the dignity of the profession. But the propriety of the interdiction of these acts by the code is not always appreciated by the public. As a reason for their being interdicted as 'highly reprehensible in a regular physician,' it suffices to say that they are 'the ordinary practices of empirics.' The public should understand that these practices are criteria of irregular or unworthy practitioners. With this understanding, if persons consent to be influenced by such acts, the responsibility for consequences lies with themselves."*

Since, then, the mass of the old code is acceptable to the larger number of physicians, why do we need a new code? This document, which has not entered the medical world without considerable artificial assistance, is, so far as the relative importance of the various paragraphs is concerned, one clause surrounded by a code. The kernel section of the whole instrument is that which permits consultations with any "legally qualified practitioner." It is a greater freedom in consultations for which the opposition is striv-

* "Medical Ethics and Etiquette." By Austin Flint, M. D.

ing. Since, however, it is admitted that the new code does not essentially differ from the old, except in that clause which refers to consultation, and since the old code commends itself in the main to the vast majority of the profession by its excellent ethical teachings, the introduction of a new code seems superfluous.

Is any code necessary? On the platform of no code meet the extremes of professional character. They meet, and yet the separation is world-wide. Some of the most honorable physicians think that the only code necessary is that which usually regulates gentlemen in their ordinary intercourse with each other. On the other hand, that comparatively small band of practitioners which rides with a free lance to seize its advantage in whatever quarter it may present itself looks with aversion upon the restraints of any code, from the golden rule down to the ordinary barriers of professional courtesy. The ideal code would presumably be one not of restraint, but rather of guidance—simply a set of rules by which the conduct of physicians toward each other in the delicate relations of practice might be indicated, and which could be used for reference in doubtful cases. These would be like the by-laws of a society, or those rules of navigation which direct the sailing of vessels. At present there are two uses of a code—one as a ready method of guidance for physicians, another as a check upon men who are disposed to take unfair advantage of their colleagues. The practice of medicine differs from that of other callings, since it combines the incongruous principles of sentiment and trade. It is doing work for money, but that for which remuneration is received is essentially unlike the objects of merchandise. The transaction in one case refers to "human creatures' lives," in the other to material substances which can be weighed and handled and have a definite value. Sometimes what are called worthless lives are in question, but even here that life is held by the patient as of more value than any other possession. If the usual laws of trade held in medicine, the rich would receive the benefit of treatment to the disparagement of the poor. As it is, the poor are often better cared for than the wealthy. By urging the adoption of sanitary laws and pointing out the causes of disease, medical men are, as it were, all the time interfering with the increase of their own business by preventing sickness. They could not do otherwise and carry out the principles of the old code. With such labor comes a sense of responsibility which raises the work above the idea of so much money for so much time, and surrounds all with the claims of duty to the sick. The physician may be discharging duties which in themselves are allied to those of the menial, or occupied with the most delicate and sacred trusts connected with the structure of society; in either case the high nature of the office transfigures the worker. If there were not written ethics concerning men who are engaged in such pursuits, they would develop from the very nature of the case; and, if this be so, why should not such regulations have the definiteness of a written document?

Is there no method for arriving at a solution of the present misunderstanding? A large number of physicians throughout the country regard the old code with feelings

of reverence. Such as these would feel greatly opposed to shelving the old document and substituting a new one. At the same time, many of them would not be averse to enlarging the liberties of physicians in consultation, or, at all events, of giving that system a trial. Many believe that regular medicine would gain ground by thus coming in contact with different varieties of practice, if such there be. The community would probably learn that many supposed grave disorders from which they suffer did not merit the serious names applied to them, and that the curative virtues attributed to the dynamics of subdivided atoms were the result of the restorative influences of unimpeded natural laws. Why, then, may not the old code be amended? It would be a concession to the large number of physicians who believe—and their faith is not in all instances influenced by any sordid motive—that in the interest of the sick a better opportunity should be given for greater freedom in consultation. The more incompetent the attendant, the more does the patient need good advice. When the strength which persecution gives to any new movement was taken away, and the search in scientific medicine was unimpeded by dissensions, the noble traditions of the old code would still remain, and what was new would be in the nature of an amendment, as amendments are made to constitutions or by-laws. Who can believe that those who advocate greater freedom in consultations are all animated by personal considerations? Men surely do form opinions on ethical matters without any regard to the result which their conclusions may have upon their individual interests, and why should it not be so in this instance? Medical men are certainly inspired by a different sentiment from this, or else the traditional spirit which has come down from early ages, and which still illustrates itself wherever medical charity exerts its beneficent offices, is on the wane. There seems to be a fair ground for a difference of opinion concerning greater freedom in consultations.

The method of settlement is somewhat difficult, since the expression of a majority does not necessarily change one's opinion. But could not some method similar to the following be adopted as agreeable to all? In case a patient or the friends of a patient who is under the care of an irregular practitioner desire the advice of a regular physician, such a physician may meet the practitioner in attendance, whoever the attendant may be. His conduct toward him can surely be that which he would adopt toward any one else whom he might meet in the ordinary relations of life. He examines the patient, gives his views of diagnosis and treatment, and retires. To continue in attendance with some one whose ideas of medicine were entirely different from his own would not contribute to the benefit of the patient. *Meeting* is not affiliation; it is the sick man who needs the advice, and, if he receives it, then it may more properly be said that the "good of the patient is the sole object in view." At present the regular physician may not, consistently with the code, meet the irregular practitioner. By an arrangement like that indicated, the sick man could receive whatever benefit might arise from a consultation without a too onerous formality. It might happen also that a patient or his friends would wish the opinion of an irregular

practitioner; here the attending physician could use his own judgment whether to meet such a one or retire from the case. The circumstances would be different, since he would not consider that the good of the patient required any such opinions, and, under ordinary circumstances, he would probably refuse such counsel, or retire if it were insisted upon.

As to the body which shall decide the question concerning greater freedom in consultation, it seems as if that decision ought to come from the American Medical Association. That organization represents the profession of the whole country more than any other. It has already given its codes for professional guidance, and it seems most proper that this office should continue to devolve upon it. In the association formed to uphold the old code of ethics there is the additional clause that this is to resist any change which does not emanate from the body in which it originated. This indicates that movements toward such a change have been contemplated, but deprecates any revolutionary or secessionary measures, which would only leave the ragged edges of division, and interfere with professional harmony. There are some, perhaps many, in the association for upholding the code who would like to see greater freedom in consultations, but who wish that the change should spring from the large representative body of the American Medical Association. Unless this change does come, there is danger of a greater alienation than now exists, and strength will be given to an opposition which, it would seem, might be reconciled for the benefit of all.

It does not by any means follow that those who defend existing institutions are more really the friends of such institutions than those who criticise or oppose them. An error is no less an error because it has received the approval of centuries than one which is just fledged. Thoughts and principles which have become embodied in documents as rules for action should be tested by the essential laws of truth and taste and common sense, and rise or fall in proportion as they correspond to such a standard.

So it seems to me that any suggestion concerning a change in that estimable declaration known as the code of medical ethics should be received respectfully and considered dispassionately. We must be ready to receive changes, for they will come, and the *fait accompli* is a stronger argument than any document or rule. When I entered the profession, the physician who used electricity as a healing agent was regarded somewhat suspiciously as of quackish proclivities, and an oculist was, as Falstaff has it, "little better than one of the wicked." The opinions of to-day show how high the tide has risen since then. An opinion is no better and no worse because it is mossy with the reverence of accumulated years. There is a conservatism which never learns and never forgets, and there is also a conservatism which does not yield readily to new opinions, but which tests the new-comers by essential laws of truth and right, and does not fear lest what is essentially necessary and true will always maintain its own vigorous power.

A QUARANTINE STATION has been established at Pensacola by the Surgeon-General of the Marine-Hospital Service.

WHAT IS A LICENSE TO PRACTICE MEDICINE?

By H. R. HOPKINS, M. D.,

BUFFALO, N. Y.

THE proposition has been stated at various times, by different writers and speakers, that the medical profession of this country holds a different relation to the people from that maintained by the profession in many parts of the old world; that this difference results from and is in harmony with our theory of government of the people, by the people, for the people.

The writer, in the course of some remarks upon the question of ethics at the recent meeting of the New York State Medical Society, in referring to this peculiar attitude of the profession to the State, maintained in particular that the relation of the State Medical Society to the law was such as of necessity to seriously influence the relations of that society to the homeopathic profession.

The premises of this conclusion being, 1. That the necessities of their work and custom have made consulting attendance to be recognized as essential to or included in the enjoyment of the rights and privileges of physicians; 2. That the New York societies, State and county, being corporations, could only adopt such by-laws and regulations as the statutes creating them authorized; 3. That there is the greatest possible difference in by-law making power between such incorporated societies and the voluntary bodies, such as the American Medical Association; 4. That it is unwise for the State Medical Society to attempt to defy, oppose, thwart, go contrary to or inconsistent with the laws of the State, the policy and theory of our government, and the temper and feeling of our times; 5. That a by-law of the New York State Medical Society, out of which can be spelled the excuse for withholding consulting attendance from any person legally qualified to practice medicine in this State, would be unauthorized, illegal, and void.

Without attempting to review or in any way controvert the foregoing premises, the author of "Medical Ethics and Etiquette" pronounces the conclusion absurd, and proceeds to mark the degree of absurdity by citing the imaginary picture of a Christian minister being obliged to exchange pulpits with and at the instance of a Mormon elder, for the reason that in the eye of the law, in this country, all religious denominations have equal rights.

The writer has the feeling that the policy of one party in the code controversy will be largely based upon the few allusions found in the fourth and last articles of the series above referred to, and for this reason their statements should receive careful examination.

Let us see how much, if any, parallelism exists between the illustration cited by our author and the situation he was supposed to be discussing.

The laws of our land do not recognize any religious belief, but simply undertake to say how the temporal affairs of religious corporations shall be managed. On the other hand, the law does recognize the practice, or the attempt to

practice medicine, and distinctly confers the rights of such practice upon certain individuals, and then only in consideration of the fulfillment of certain preliminary conditions upon the part of the candidates for such rights. Any one so minded can at any time become a Christian minister or a Mormon elder; but let him attempt to practice medicine without first complying with the preliminary conditions, and the hand of the law is at once laid upon him in heavy penalty.

Again, the Mormon elder may teach any amount of pernicious doctrine, and the people suffering therefrom have no redress; but let a physician give bad advice, or neglect to take due and proper care of his patients, and the law holds him responsible for any damages occurring therefrom. In fact, it is hard to conceive of two classes more dissimilarly related to the law than religious teachers and physicians.

Another objection to the illustration is, that neither the minister, the elder, nor their respective hearers have any wish for such interchange of services, while there is not a day that the people do not solicit the attendance of physicians in consultation with homœopaths, and can never be made to see any good reason why such consultation should be refused.

I submit it to the candid men of our profession, that there is no possible disposition which can be made of this illustration to throw light upon the question of the codes, and that in its use its author has left the domain of argument and instructive writing, and is appealing to the class prejudices, the party pride, the intolerance of a profession which frequently remarks its own liberality.

It may be said in reply that ridicule is ever an appropriate answer to absurdity, but where, as in this case, the sentiments were first announced by eminent fathers in medicine, and bear the unanimous indorsements of the American Medical Association and the New York State Medical Society, where the same principles are to be found in the decisions of the highest courts of the land, would it not be in better form to show cause why such sentiments no longer merit serious consideration?

Again, the highest professional society in this State, the Medical Society of the State of New York, has for the past two years been under the control and direction of men holding this view of the necessity of recognizing the relations of the homœopath to the law. Does not the ignorance of men so conspicuously placed merit an attempt at enlightenment?

It is said that the new code is a well-nigh everlasting disgrace to the profession. In view of such great danger to all, is it not worth while to reason with its supporters, to show them the error of their views? In case the position is so plainly untenable, it would require much less space than that of six articles and a conclusion to show, step by step, that untenability.

To be sure, it is not always easy to be considerate and patient with those whose views oppose our own, particularly when the new view carries a reflection upon the wisdom of a long-established doctrine and usage; but are we not members of the same profession? are we not still eligible to consultation? do we not give the grounds for our views, and

can we not agree that the premises upon which a conclusion is based are more important than any man's conclusion?

I trust the author of the articles on "Medical Ethics and Etiquette" will pardon some remarks, offered in a spirit of inquiry, upon the positions advanced by him. At page 455 ("Concluding Remarks") he says: "The question, therefore, now at issue in the State of New York is simply this: Shall consultations with homœopathic practitioners be permitted? . . . As regards the legal status of homœopathic practitioners, this has nothing to do with the question. It would be strange, indeed, if a State Legislature should undertake to regulate the professional ethics of physicians. This has never been attempted, and it probably never will be."

One's first impulse upon reading these declarations is to adopt the method of its author, just criticised, and to generalize; but, instead of this, I will try and set forth reasons why the assertions here given are not competent guides in this crisis.

I have tried, and in vain, to put myself in the place of the author of these lines, for the purpose of apprehending what was in his mind when he wrote that the Legislature never had undertaken, and never would undertake, to regulate the ethics of the medical profession of this State.

The only approach to a theory which I can reach is, that, to the author, medical ethics means something as delicate, as immaterial, as unsubstantial, and as impracticable as the vagaries of the fashions of the ultra-polite. That its nearest approach to practical realization might be seen in the rule determining the order in which the members of a consultation should deliver their opinions, or the order in which, with several present, they should leave the room. Matters of this moment the Legislature probably has not attempted, and will not attempt, to regulate.

But can it be possible the author means what he says when he excludes from the operation and control of the law all those matters embraced by the code of ethics he has taken so much space to explain and illustrate?

In case this is his meaning, the following will at least cast doubts upon its validity:

The code of ethics exerts its influence upon the medical profession by virtue of being a by-law of some society of which the individuals are members, and that society is not the American Medical Association, not even a State medical society, but is much smaller and more localized than these, and in this State is the county medical society. The quotations above cited make the most remarkable assertion that the Legislature never has attempted, and probably never will attempt, to regulate the by-laws of county medical societies.

Chapter 138, laws of 1806, the same being the act incorporating State and county medical societies, provides "That it shall and may be lawful, for the respective societies to be established by virtue of this act, to make such by-laws, rules, and regulations, relative to the affairs, concerns, and property of said societies, relative to the admission and the expulsion of members, relative to such donations or contributions, as they or a majority of the members, at their annual meetings, may think fit and proper.

"Provided, That such by-laws, rules, and regulations, made by the Society of the State of New York, be not contrary to nor inconsistent with the constitution and by-laws of this State or of the United States, and that the by-laws, rules, and regulations of the respective counties shall not be repugnant to the by-laws, rules, and regulations of the Medical Society of the State of New York, nor contrary to nor inconsistent with the constitution and laws of this State or of the United States."

This attempt on the part of the Legislature to regulate the by-laws, rules, and regulations, including the medical ethics of the profession, has been construed by the courts at various times, the following instances having fallen under my observation :

The Medical Society of the County of Erie adopted a resolution declaring that it was a violation of medical ethics to undertake to do a certain work for less than a fixed price. A member, one Gray, undertook the work for less than the sum named, and, this coming to the notice of the society, he was promptly expelled therefrom. Litigation followed, the members were roundly taxed for the incident expenses, and in the end had the pleasure of learning this lesson from the final decision of the courts, which can be seen in Barbour, vol. xxiv, page 570.

The Court held: "A by-law must not be at variance with the general law of the land; it must be reasonable, and adapted to the purposes of the corporation. The regulation in question was unauthorized. It was unreasonable. It was against public policy and the law. The disfranchisement of the relator was unauthorized and illegal. It follows that he must be restored or recognized as a member of the medical society, and be permitted, without molestation, to enjoy all the rights and privileges of a member."

A few years later the same society undertook to exclude one Bartlett for an alleged violation of a regulation of the society, its code of ethics—that now held by the American Medical Association. After another long and expensive litigation, the society again learned, in the most positive manner, that the law could construe the said code, and that it could, would, and did fix the limits of its operations. This pertinent ruling can be found in the New York Reports, vol. xxxii, page 187.

These instances occurred in my own county society, and bear the most positive testimony to the fact that the law recognizes, and, if need be, regulates, the ethics of physicians.

It is worthy of remark that in both of these cases the dominant feeling in the society was quite in accord with that expressed in the quotations under discussion, and, therefore, perfectly in accord with most of the declamation which has been launched at the supporters of our present code; and it may be worth remembering that the process of schooling experienced by the Erie County Society, which seemed necessary to the unlearning of this error, was at once irritating, humiliating, and expensive.

The writer is quite positive that, in case the profession at large were to pass such a pupillage, they would in the end easily agree that it would have been by far both more

creditable and more satisfactory to have discovered and corrected the error of the position, even if that error had been of *thirty-six years' standing*.

The most concise, exhaustive, and pertinent statement of the relations of the individual to the profession of medicine, the relations of the profession to the people, that has fallen under my eye is to be found in the decision of Aiken *vs.* The State Board of Health of Illinois. This case was brought to test the constitutionality of the Medical Practice Act of that State. The following quotations are from the decision of the Circuit Court of Cook County, which decision was affirmed by the Court of Appeals:

"What is a license to practice a profession? Is it a constitutional privilege? Is it a property? Is it a contract? In a certain sense, it is true that every man has a natural right to follow out the bent of his inclination and be a clergyman, a lawyer, a doctor, a scavenger, a peddler, an auctioneer, just as he may choose. *But it is not true that a man can practice any of these professions or occupations except he does it upon such terms as the law imposes, and the law can impose just such terms upon any of these professions or employments as the legislators in their discretion deem most for the interest of the community. If, then, a man has a natural right to be a lawyer or a doctor, he possesses that right subject to every restriction which the law may have created before, or which it may create subsequent to his entrance upon the given profession. In no sense can the words 'property' and 'contract' be applied to the right to practice medicine.*"

By virtue of this right to impose terms and restrictions upon the individual members of the profession, the people, through their representatives in the Legislature, undertake to regulate even the professional ethics of physicians. Not only is this the case, but, more than this, the Legislature expressly declares that the privileges granted the profession to-day may be forfeited and taken away to-morrow, so that one can in truth say that *the Legislature regulates the professional ethics of physicians from day to day*. In making this assertion, the writer has in mind practical ethics—ethical provisions for the violation of which a physician would be liable to discipline, rather than matters of fashion or etiquette.

The writer would not presume to come before the profession with even a suggestion upon this subject were it not for the belief, as he has before stated, that the code controversy exists because of the different views held by medical men upon the nature of the rights of physicians. When we can have some approach to uniformity of belief as to "what is a license to practice medicine," we shall have made quite an advance toward the greatly to be desired unanimity of feeling upon the question of the codes.

There would seem to be upon the part of many of our members a feeling of irritation at the mention of the relation of the medical profession to the law, and a desire to repudiate any such relation, as if we were thereby humiliated. I know of no better remedy for this undue sensitiveness than to dwell upon the grand words of Bishop Hooker, with which I would close:

"Of Law no less can be acknowledged than that her seat

is the bosom of God, her voice the harmony of the world. All things in heaven and earth do her homage, the very least as feeling her care, the greatest as not exempt from her power."

Book Notices.

A Manual of Obstetrics. By A. F. A. KING, M. D., Professor of Obstetrics and Diseases of Women and Children in the Medical Department of the Columbian University, Washington, D. C., etc. Philadelphia: Henry C. Lea's Son & Co., 1882. Pp. xx-25 to 325, inclusive.

In this work, which comprehends the physiology and pathology of pregnancy, the puerperal diseases, and some medico-legal matters connected with the function of child-bearing, together with what constitutes practical obstetrics in a strict sense, it must be confessed that the author has succeeded in avoiding in great measure the shortcomings that are apt to creep into a condensed text-book. While not professing to be more than a manual, and therefore lacking the argumentative element that is needed to impart a thorough understanding of our present knowledge of obstetrics, the book presents the leading points of that art in a plain and intelligible manner, and, so far as we have observed, with accuracy. It ought, therefore, to take a prominent place among the works that are used for hasty reference.

The Change of Life in Health and Disease. A Clinical Treatise on the Diseases of the Ganglionic Nervous System incidental to Women at the Decline of Life. By EDWARD JOHN TILT, M. D., Past President of the Obstetrical Society of London. Fourth edition. Philadelphia: P. Blakiston, Son & Co., 1882. Pp. 184. [Price, paper, 75c.; cloth, \$1.25.]

In the dearth of literature bearing upon the physiology and pathology of the menopause, Dr. Tilt's work is of considerable value as embodying a collection of odd facts and deductions connected with those subjects. The "change of life" is certainly deserving of more study at the hands of the profession than it has received, and the author of this book will have deserved well if it succeeds in leading to such a study.

Dysmenorrhœa: its Pathology and Treatment. By HEYWOOD SMITH, M. A., M. D., Oxon., Physician to the Hospital for Women and to the British Lying-in Hospital, etc. London: J. & A. Churchill, 1881. Pp. x-122.

DR. SMITH considers the various morbid conditions that are supposed to give rise to dysmenorrhœa, comprising affections of the ovary, of the oviduct, of the pelvic peritoneum and cellular tissue, and of the uterus, together with certain diathetic conditions. This is undoubtedly the correct way to study dysmenorrhœa, and we trust that it will some time lead us to a better knowledge of its pathology than we now have.

As regards treatment, we can not say that the author has put forward anything specially noteworthy. Rather contrary to the general tendency of opinion at the present day, he still regards Sims's operation as the measure best calculated to bring about a cure in cases of congenital ante flexion.

He thus speaks of oöphorectomy for ovarian inflammatory dysmenorrhœa: "I consider the cases most favorable for operation those in which there is severe dysmenorrhœa undermining the health of body and mind, where the pain is due to extreme congestion of the ovaries, and more so in those cases where

prolonged congestion or inflammation . . . has led to that form of disease termed cirrhosis, when, as a rule, the ovaries are non-adherent."

Some attention is devoted to vicarious menstruation and to hysteria, but of rather a fragmentary sort. Indeed, all through, the book lacks thoroughness in matters of detail. Nevertheless, it strikes us as a contribution of considerable value.

Contributions to Practical Gynecology. By S. JAMES DONALDSON, M. D., Fellow of the New York Medico-Chirurgical Society, etc. New York, 1882. Pp. 134. [From J. H. Vail & Co.]

DR. DONALDSON'S brochure deals chiefly with uterine flexions and with dysmenorrhœa. We find many evidences of good sense in its pages, but also a proneness to a degree of confidence in pessaries that we can not share, and a decided fondness for particular instruments of the author's own invention.

BOOKS AND PAMPHLETS RECEIVED.

Deep Breathing as a Means of Promoting the Art of Song, and of Curing Weaknesses and Affections of the Throat and Lungs, especially Consumption. By Sophia Marquise A. Ciccolina. Illustrated. Translated from the German by Edgar S. Werner. New York: M. L. Holbrook & Co. Pp. 48.

Lectures on Medical Nursing, delivered in the Royal Infirmary, Glasgow. By J. Wallace Anderson, M. D., Lecturer on Medicine, Royal Infirmary Medical School, etc. Second edition. New York: Macmillan & Co., 1883. Pp. x-224. [Price, \$1.]

La Pella a Desio (Provincia di Milano). Noterella del Dottor Vittorio Cavagnis, Medico Condotta Locale. Milano: Fratelli Rechiedei, 1883. [Reprint from the "Gazzetta Medica Italiana-Lombardia."]

Alcohol as a Food, a Medicine, a Poison, and as a Luxury. By George C. Pitzer, M. D., Professor of the Theory and Practice of Medicine in the American Medical College, St. Louis, etc. St. Louis, 1883. Pp. 46 to 61, inclusive. [Price, 25c.]

Inquiries into Human Faculty and its Development. By Francis Galton, F. R. S., author of "Hereditary Genius," etc. New York: Macmillan & Co., 1883. Pp. xii-387. [Price, \$3.]

Lectures on Cataract: its Causes, Varieties, and Treatment. Being Six Lectures delivered at the Westminster Hospital. By George Cowell, F. R. C. S., Senior Surgeon to the Westminster Hospital, etc. With illustrations. London: Macmillan & Co., 1883. Pp. xv-126. [Price, \$1.50.]

Report on the Pharmacopœias of all Nations. By Dr. James M. Flint, U. S. N. Washington: Government Printing Office, 1883. Pp. 28. [Extracted from the Report of the Surgeon-General of the United States Navy for 1882.]

Cases of Mushroom Poisoning. By James D. Trask, M. D., of Astoria, N. Y. [Reprint from the "American Journal of the Medical Sciences."]

The Microscope and its Revelations. By William B. Carpenter, C. B., M. D., LL. D., etc. Sixth edition, illustrated by twenty-six plates and five hundred wood engravings. Volume II. New York: William Wood & Co., 1883. Pp. iv-354. [Wood's Library of Standard Medical Authors.]

Hand-Book for Friendly Visitors among the Poor. Compiled and arranged by the Charity Organization Society of the City of New York. New York: G. P. Putnam's Sons, 1883. Pp. iv-88.

The Official Correspondence between Surgeon-General William A. Hammond, U. S. A., and the Adjutant-General of the Army, relative to the Founding of the Army Medical Museum, etc. New York: D. Appleton & Co. Pp. 8.

NEW YORK, SATURDAY, JUNE 2, 1883.

THE MEETING AT CLEVELAND.

DURING the early years of its activity the American Medical Association, although small in numbers, was perhaps more truly representative of the profession at its best than it has been since its membership has swollen to the proportions that its peculiar mode of growth could not fail to bring about. For this reason, probably, and because membership has consequently been coming to be less of a distinction year by year, its annual meetings have progressively been viewed with greater interest by the many, while the select few, whose peers at first made up the organization, have felt continually more and more conscious that whatever part they might take in the proceedings would be inconspicuous and perfunctory, and that attendance was becoming to them more of a duty and less of a pleasure.

The element first mentioned—the rank and file of the profession—naturally find themselves more closely drawn to the association year by year, for the chances are continually multiplying by which any one of them who has deserved well of his fellows may find himself invested with the privileges and the dignity that attend membership. Once a delegate, always a member, is doubtless a consideration that encourages the ambition of thousands of toiling physicians throughout the land, and sweetens their daily life under the load of care and vexation with which it is their lot to struggle; for, large and democratic as the association has become, it still casts a certain halo of distinction about the great majority of those who succeed in placing their names on its roll. Who shall say that, in this respect at least, it is not a blessing to the great mass of us?

On the other hand, the few who stand more and more aloof from it as succeeding years add to their own individual luster, while they dim any reflected glory that might in the past have come to them from the association, dwell upon what they consider its decadence, alleging that its scientific work is below the level of what is accomplished by local societies, that it gives the palm not so readily to him who has deserved it as to him who represents a section not before honored, and that it is annually becoming an easier and a more tempting prey to the unscrupulous manipulator. It is to be feared that these gentlemen do not sufficiently realize the fact that, were they to attend the meetings more regularly, and to take a little more pains to make themselves heard in the councils of the association, what they now account its shortcomings might be mended most materially.

In saying this we do not conceal from ourselves that the association has many disadvantages to contend with that seem insurmountable. First of all, the vast territorial extent of our country, favorable as it is from some points of view, is un-

doubtedly in one respect a drawback to that ideal status that we would fain see reached by our national organization. It must ever be the case that the large cities will be the homes of the greater number of those who are most fitted to lend *éclat* to such meetings. It is true at present, and probably will be for many years to come, that most of those cities are on the Atlantic seaboard, whereas the association is likely to meet anywhere from five hundred to three thousand miles away. The idea is cherished by many of those who have the welfare of the association most at heart that it is quite feasible for it to tread close upon the heels of its prototype, the British Medical Association. But our British brethren are happy in their "right little, tight little isle"—from London, which, from a literary and scientific point of view, is practically all England, a busy man may make the journey to whatever town the British association may select for its meeting, read his paper, the outcome of a year of reflection, and get back home again, almost without deranging his consultation appointments. For one of our metropolitan practitioners to take part in a meeting of the American Medical Association means, however, the necessary sacrifice of the better part of a week.

We are far from meaning to say that city men are all in all to a national scientific body. Indeed, that is notoriously not the case as regards associations devoted to pure science; but, when we consider that medicine has an important aspect that is purely commercial, we can only repeat that the medical magnet finds his natural habitat in the great centers of population, of trade, and of wealth. While we confess that it would be a hardship for our southern and western brethren to make their pilgrimage always to Boston, New York, Philadelphia, Baltimore, or Washington, it may eventually seem to the American Medical Association, as it already has seemed to some of the special national societies, better on the whole to decide that the meetings shall always be held in one of the great Atlantic towns. Nevertheless, this year the attractions of Cleveland, if nothing else, are likely to bring a memorable meeting to pass.

THE ETHICAL QUESTION AND THE AMERICAN MEDICAL ASSOCIATION.

It is not easy to see how the question of the expediency of modifying the code of ethics of the American Medical Association can fail to come up, in one form or another, at the forthcoming meeting of that body. It is certain, however, that it will not be brought up at the instigation or with the consent of the party that has secured the adoption and confirmation of the present code of the Medical Society of the State of New York, for that party has no expectation that its success in its own State will materially affect the position taken by the great majority of those who are to assemble at Cleveland, and it is not willing to play the part of a suppliant. It trusts rather to the logic of events, and is content to abide its time; satisfied that it can look to no concession from the national association, it is firm in the conviction that it stands in no need of such concession. Indeed, it seems not improbable that it would rather dislike to find itself in a position that public opinion would regard as calling

for counter-compromise on its own part, for such a recession from the firm stand it has maintained would involve what it could not but consider as an abandonment of an advantage already gained. Successful revolutionists do not sue for terms; the cry for peace is wont to come from those who are getting the worst of it.

And yet, as our contributor, Dr. Piffard, very properly insists, the attitude of the profession in the State of New York is not that of "rebellion" against constituted authority, for the authority it never recognized. On the contrary, it is one of voluntary renunciation—temporary, it is hoped—of certain present and material advantages for the sake of the ultimate triumph of a principle. New York acts not with an overweening idea of her own importance, but with a full appreciation that, in taking the stand she has taken, she entered upon a course of which every unpleasant consequence was foreseen and accepted as the necessary concomitant of the move she believed herself to be making in the interest of the whole American profession, and with confidence that the purity of her motives and the wisdom of her action will be acknowledged in the end. This we judge to be the attitude of the new-code party.

As regards the old-code party in the State of New York, the case is different. This party is on the defensive, and, consequently, burdened with the inertia that always accompanies a quasi-negative position. Notwithstanding its pronounced, not to say frantic, utterances, the rank and file lack enthusiasm. To attain a result far short of creating enthusiasm—that, namely, of securing a half-hearted adhesion to the cause, nothing more than nominal at present, and to be raised to the pitch of reality by contingent events if at all—the promoters of the movement now going on in the State of New York in favor of the restoration of the old code have found it necessary to induce many to lend countenance to their contention by assurances that they did not indeed regard the old code as altogether what it should be, and that they would use their best endeavors to secure its speedy modification. To be explicit, it is well known that many of those who have signed the declaration stating that they were opposed to any alteration of the code of ethics of the American Medical Association that did not emanate from that body, have so signed only on the earnest solicitation of canvassers, coupled with the pledge that steps would be taken as soon as practicable to bring the old code into consonance with the views of these signers. Many who signed under those representations have declared themselves really opposed to all codes, but state that, being conservatives by nature, they consented to attach their names to the declaration in question because, after much deliberation, they thought it best that any change in our ethical regulations should be uniform throughout the whole country, and therefore should come from the only organization that has any pretension to represent the American profession as a whole.

Such being the case, the promoters of the movement in favor of the restoration of the old code in this State seem bound not only by honor, but also by interest, to do their best to achieve

a tangible modification of that code by the American Medical Association—by interest, not to weaken the forces of their opponents, for that they can not hope to do, but merely to retain their own nominal following. Moreover, no mere *pro forma* display will satisfy the latter; they want not only an earnest but a successful effort, in default of which they will transfer their allegiance.

This brings us to the question: Is such successful effort possible? We take it for granted that the Cleveland meeting can not definitively enact any change in the code, for such action, being of the nature of an amendment to the by-laws, must lie over for a year. Should the association see fit to put such a proposition *en train*, however, the meeting of 1884 would be in a position to take final action in the light of whatever may transpire at Albany next February. But it does not seem likely to us that this course will be pursued, in case the question comes up. Several State delegations are under instructions to vote down all changes of the code that may be proposed, and the sentiment of many State societies that have not instructed their delegates is so obviously and radically adverse to any concession that it is almost certain that no change can be put in the way of accomplishment. Judging from all the data at our command, then, no proposition looking to a substantial modification of the association's code is likely to be urged with any warmth, or, if so urged, is destined to meet with any more favorable action than a reference to the judicial council—which means its strangulation.

THE STUDY OF PHYSIOLOGY IN ACADEMICAL COURSES.

In a recent number of the "Educational Times" we find a paper, read before the College of Preceptors, by Dr. Allchin, of the Westminster Hospital, London, who takes decided ground against the utility of physiology as a subject of elementary education. Dr. Allchin states that for nearly twenty years past he has been engaged in the study and teaching of physiology, and as an examiner in that branch. The result of his observation has been that, as a general thing, pupils who make physiology a part of their academical course learn at the most but a few salient and detached facts, that what they learn is so fragmentary as to be of no practical service to them in their subsequent career, and that, making no approach to a grasping of the science of the subject, their minds are not appreciably trained by that study, as they are by some others that are of no particular service as mere acquirements. In view of these considerations, Dr. Allchin is emphatically of the opinion that the study of physiology under such circumstances is worse than useless.

It is the besetting error of teachers of special branches to magnify the importance of those branches and set them above all others whatsoever, insisting, in season and out of season, upon the necessity of their study by all classes of pupils, and for all sorts of reasons. Dr. Allchin is certainly to be credited with having risen above the propensity in question, and we may say, moreover, that his paper is an exceedingly able presentation of the subject from the point of view taken. Nevertheless, we doubt if the conclusions are quite warranted by the

facts. It is the common experience of teachers that very few of their pupils seem to grasp a difficult subject, and yet it is a matter of every-day observation that men who in their school-days seemed to get no discernible insight into a particular study give practical evidence of having, after all, imbibed a very fair idea of it, as shown not only by the memory of disjointed facts, but also by the marked facility with which, on taking the subject up anew, they master it, although in the mean time they may have given it no attention whatever. In such cases the assimilation of knowledge, if we may use the expression, is a matter of time, and goes on unconsciously, remaining latent, so to speak, and utterly eluding the examiner's art.

Then, again, in the matter of physiological study considered as a means of developing the mental powers, such an effect may not be apparent at once, but surely something must be accomplished by it in that direction, for it appeals to the ingenuity, the speculative tendency, and the judgment, we should say, as few other studies do. As with any other, much depends, of course, on the teacher; but, given the same intelligence on the part of the pupils and an equal power of imparting knowledge on the part of the teacher, it is not easy to see why the study of physiology should prove less valuable in an academical course than that of any of the other branches that are commonly pursued at the same time.

THE PRESIDENCY OF THE AMERICAN MEDICAL ASSOCIATION.

It has been thought for some time past that Dr. Austin Flint would be chosen president of the association at its approaching meeting, and the proposition has now been formally made by one of our contemporaries, the "Louisville Medical News." It is not alone in New York that such a choice would be regarded as a graceful act on the part of the association, but throughout the whole country. This we say not merely because Dr. Flint's services to medicine are everywhere held in high esteem, but particularly because at the present time his accession to the office in question would, we think, have a pacifying influence on ethical extremists of either side.

Proceedings of Societies.

AMERICAN LARYNGOLOGICAL ASSOCIATION.

(Concluded from page 585.)

Afternoon Session—First Day.

THE DESTRUCTION OF NASAL POLYPI BY CHROMIC ACID was the title of a paper read by Dr. FRANK DONALDSON, of Baltimore. The point to be aimed at in the treatment of polypi of the nasal passages was prompt and rapid removal, with a minimum degree of pain and loss of blood, and in a manner to prevent their recurrence. The author then spoke of the advantages and the disadvantages pertaining to the three methods of treatment commonly employed—that by the forceps, by the galvanic cauter, and by the use of escharotics. According to his experience, the conditions before mentioned were best fulfilled by an application of fine crystals of chromic acid, or of a solution

of a hundred grains to the ounce, first moistening the mucous membrane with a lead lotion. Chromic acid was a most powerful escharotic, and also disinfectant. When instruments were used, it was of advantage first to apply the acid to the base of the growth and lessen the size of the pedicle; or afterward to the stump, destroying it completely.

Dr. W. C. JARVIS, of New York, thought that usually the development of nasal polypi near the seat of a former operation took place not from the roots of the polypi that had been removed, but from embryonic structure upon the mucous membrane in the immediate neighborhood which now had room for growth. The application of chromic acid after removal of the large tumor by the wire would prevent this.

Dr. W. F. DUNCAN, of New York, thought that recurrence of the polypus could be guarded against only by removal of a portion of the turbinated bone from which it sprang. In his experience there had been a recurrence in about eighty per cent. of the cases within from one to five years after the growth had been removed by other methods.

Dr. CARL SEILER, of Philadelphia, had found that polypi of the gelatinoid variety were a localized hypertrophy of the mucous membrane which had undergone myxomatous degeneration. In their removal he preferred the wire, which, when tightened slowly, gave rise to less pain than did escharotics. A recurrence did not take place if all the growths were removed.

Dr. W. H. DALY, of Pittsburg, had used chromic acid with satisfaction, but he had found one escharotic about as good as another.

CHOREA LARYNGIS.—Dr. FREDERICK I. KNIGHT, of Boston, read a paper on this subject, in which he spoke of three varieties, viz.: That in which the adductors of the larynx were involved, together with the expiratory muscles, giving rise to paroxysms of coughing, and a barking or crowing sound; second, that in which the muscles of the larynx alone were involved; third, but not properly belonging under this head, that in which the expiratory muscles alone were involved. The author mentioned a case which, so far as he was aware, was unique, in which the laryngeal muscles alone were involved, and a clicking sound, heard by himself and by the patient, was produced, apparently, by the rhythmical contraction of the vocal cords. Arsenic and quinine had had but little effect upon the spasm.

Dr. S. W. LANGMAID, of Boston, had seen the case with Dr. Knight, and spoke of the remarkable rhythmical movement of the vocal cords alluded to.

Dr. E. C. MORGAN, of Washington, mentioned the case of a girl which fell under the class of cases in which both the laryngeal and the expiratory muscles were affected, and the crowing cough could be heard the distance of a square. He had obtained most benefit from Fowler's solution and monobromated camphor.

Dr. E. F. INGALS, of Chicago, referred to a case in which there were peculiar movements of the levator palati muscle, each contraction of the muscle being accompanied by a clicking sound.

Dr. LANGMAID remarked further, with regard to treatment, that in one case falling under the first division, which he believed had been excited by the influence of harsh methods of the music teacher upon the nervous system of the patient, the barking sound was found always to be preceded by opening the mouth. The girl carried out his instructions to close the mouth immediately when an attack was about to occur, and it was thus aborted.

THE TREATMENT OF LARYNGEAL PHTHISIS.—Dr. E. FLETCHER INGALS, of Chicago, read a paper with this title, in which he said there were three prominent indications for treatment: First, to relieve pain; second, if possible, to cure the disease;

third, failing in this, to so modify the course of the affection as to prolong the patient's life. Pain could generally be relieved by topical applications, even though internal medication proved of little avail. The second object might sometimes be attained by topical and internal medication combined. Thirdly, life might at least be prolonged by relieving pain and enabling the patient to swallow, and preventing failure from lack of nutrition. Cases in practice were cited. He had derived great benefit from a topical application of a lotion composed of morphia, carbolic acid, tannin, glycerin, and water; also from the use of eucalyptol. Topical applications of iodoform had not proved of much benefit in his hands. Constitutional treatment and change of climate were referred to.

THE HEALING OF ULCERS IN LARYNGEAL PHTHISIS.—**DR. WILLIAM C. JARVIS**, of New York, read a paper with this title. The author gave the history of a case of phthisical ulceration of the larynx in which the right vocal cord was almost entirely eroded, and in which there were all the peculiar signs of laryngeal phthisis. A well-known expert examined the patient, and stated that there were undoubted evidences of pulmonary phthisis. The patient was unable to swallow, and her condition had become very pitiable indeed. A very unfavorable prognosis was given. The treatment was general and local. Directions with regard to the taking of food, remedies for the relief of cough, pain, sleeplessness, and nervousness were prescribed, and iodoform was applied to the ulcer. The patient changed climate. Much to his surprise, on her return he saw a woman apparently well, and she claimed to be so, for all the symptoms from which she had so severely suffered had disappeared, and she had gained in flesh. The ulcer had healed. There were still signs of pulmonary phthisis. Dr. Jarvis also showed an instrument which he had invented for the application of medicated powders to laryngeal ulcers.

DR. JOHNSTON, of Baltimore, referred to a case of laryngeal phthisis which he had been enabled to follow from before the time when signs of pulmonary phthisis could be detected. The laryngeal ulcers in that case healed under treatment.

DR. DONALDSON, of Baltimore, thought that much could be done in these cases toward prolonging the life of the patient by feeding through the stomach-pump.

DR. F. H. BOSWORTH, of New York, thought that many cases of ulcer of laryngeal phthisis which had been reported as having been cured were not such in fact, but were of a catarrhal origin, and he pointed out the differential signs between the two varieties. He remarked that the laryngeal ulcer did not cicatrize; the morbid growth simply stopped, and the surface of the ulcer took on a glazed appearance.

The paper was further discussed by Dr. Cohen, Dr. Knight, Dr. Asch, Dr. Major, Dr. Ingals, and Dr. Jarvis.

PARALYSIS OF THE CONSTRUCTOR MUSCLES OF THE PHARYNX, SIMULATING SPASMODIC STRICTURE OF THE ESOPHAGUS, WITH REPORT OF CASES.—**DR. BOSWORTH** read a paper with this title, in which he stated that the condition referred to was purely myopathic in character. In the first case mentioned, no reflex excitability of the pharynx could be called forth; in the remaining cases the paralysis was not complete, but the patients in most instances were unable to take solid foods. The treatment in each instance was by rest, the interdiction of solid food, the use of strychnine, fresh air, and bathing, and in all but the first case it proved successful; the patients were dismissed cured. Dr. Bosworth then made some remarks upon the fact that there is a greater tendency in muscles which are most overworked first to break down. This was more noticeable in muscles covered by mucous membrane, the frequent seat of inflammation.

The paper was discussed by Dr. Cohen, Dr. Langmaid, and Dr. Knight.

Second Day—Morning Session.

ON PHOTOGRAPHING THE LARYNX.—**DR. THOMAS R. FRENCH**, of Brooklyn, read a paper on this subject. The paper was a description of improvements upon the method of photographing the larynx, described at the last session. The results were summed up as follows: First, better photographs had been taken with the stationary apparatus than those of last year; second, a camera had been arranged to be held in the hand; third, the photographs were taken instantaneously by dropping a shutter; fourth, the parts reflected in the mirror were alone exposed; fifth, as the apparatus was so small, and exposure was made instantaneously, if desirable, photographs could be taken without the patient being aware of the object of the procedure; sixth, several diseased conditions of the larynx had been photographed; seventh, copies of the rhinoscopic image had been photographed, so far as he was aware, for the first time.

CONGENITAL TUMOR OF THE LARYNX, WITH A REPORT OF CASES.—The paper was written by **DR. H. A. JOHNSON**, of Chicago, and gave the history of five cases of papillomatous tumors of the larynx, in one of which the growth was coughed up spontaneously; in three tracheotomy was performed by himself or by other physicians, who also saw the patients, in one instance death taking place within twenty-four hours after the operation, and in the other two from pneumonia developing subsequently to the operation. In each case the symptoms had dated back to infancy, indicating that the tumor was congenital.

DR. KNIGHT thought it was better to let the growth alone until the child was old enough to allow of its removal by the natural passages, if in the mean time it were not expelled spontaneously. If thyrotomy were performed, the voice would be permanently injured, and the growth would probably recur.

DR. J. SOLIS COHEN, of Philadelphia, thought that the liability of the cicatrix, consequent upon the operation, to interfere with proper development at puberty constituted a serious objection to surgical interference.

The paper was further discussed by Dr. Roe, of Rochester; Dr. Major, of Montreal; and Dr. Duncan, of New York, who narrated cases of congenital tumors of the larynx.

LARYNGEAL PARALYSIS FROM ANEURYSM.—A paper on this subject, by **DR. WILLIAM PORTER**, of St. Louis, was read by title.

Afternoon Session.

REFLEX PHENOMENA DUE TO NASAL DISEASE, by **DR. LOUIS ELSBERG**, of New York.—The author's attention had been called to the fact that serious reflex phenomena might be excited by nasal disease as long ago as twenty years, when he cured a very severe case of chorea simply by treatment directed to nasal catarrh. Among the diseases falling under this class of which he had seen examples were melancholia, chorea, epilepsy, neuralgia, headache, digestive disturbances, reflex troubles pertaining to the upper air passages, uterine disorders and affections of the genito-urinary mucous membrane, disorders of smell and taste, various alterations in the speaking and singing voice, bronchial asthma, etc. He called attention to the fact that diffuse external redness of the nose was often dependent upon chronic nasal catarrh. He mentioned the case of a man suffering from chronic nasal catarrh who was always seized with severe sneezing during coitus. The author concluded his paper by quoting the remarks of Dr. A. Jacobi upon this subject, made at a meeting of the New York Obstetrical Society, 1883. [See the April 7th number of this journal.]

DR. J. N. MACKENZIE, of Baltimore, referred to a paper which he had before one of the Baltimore medical societies, in which, from experimental and clinical observation, he reached the fol-

lowing conclusions: First, that in the nose, as well as in the pharynx, there existed a definite circumscribed area, irritation of which was capable of producing a series of reflex phenomena, but especially cough. This area corresponded, in all probability, to that portion of the mucous membrane which covered the posterior cavernosum. Second, reflex phenomena were only produced when this area was irritated, all parts of which, however, were not equally sensitive. The susceptibility to reflex cough also varied greatly in different persons.

Dr. J. O. ROE, of Rochester, believed that most cases of asthma, especially hay fever, were due to chronic disease of the nose.

Dr. SEILER, of Philadelphia, mentioned the case of a girl taken suddenly with acute coryza, which brought on a severe primary attack of chorea. The choreic symptoms disappeared with the coryza. He also spoke of a case of profuse watery discharge from the nose, coming on suddenly and lasting for about three quarters of an hour, and attended by headache.

Dr. BOSWORTH thought the last case referred to by Dr. Seiler was purely nervous in character, but that it should not be classed as a case of coryza. The cases were exceedingly rare, there being but about six on record. The fluid, as he had demonstrated by microscopical and chemical examination, was almost pure water. He referred to some cases of distressing spasm of the glottis due to atrophic rhinitis, and relieved by moisture with salt water. He did not believe that chronic thickening of the nasal mucous membrane or that nasal polypi occurred in children, as stated in the quotation from Dr. Jacobi; the condition seen was glandular tissue.

SMELL, HYGIENICALLY AND MEDICO-LEGALLY CONSIDERED.—This paper was read by Dr. CLINTON WAGNER, of New York, who gave a definition for odor and smell, spoke of the high state of development of the sense of smell in certain of the lower animals, and in certain persons from cultivation, especially in those deaf and dumb, and those engaged in sampling cigars, flour, etc.; of the conditions in which it might aid in the preservation of the health by the detection of odors arising from unhealthful conditions, and of aid to the physician in diagnosis. Some of the diseases which gave forth a peculiar odor were the following: Alcoholic coma, mercurial pyalism, exanthematous and other febrile diseases, the lying-in state, stercoraceous vomiting, etc. One author stated that the habitual masturbator had the odor of liquor annii.

Dr. BEVERLEY ROBINSON, of New York, called attention to the importance of making a distinction between disinfection and deodorization.

Dr. C. W. CHAMBERLAIN, of Hartford, mentioned an instance in which all the occupants of a house, whose sleeping apartments were exposed to the odors from a certain factory, suffered from a spasmodic affection of the larynx.

Dr. S. H. CHAPMAN, of New Haven, remarked that odor in itself was of no importance to the physician unless it also carried the germs of disease. The idea was best expressed by the German doctor when an old lady entered his office and said: "Doctor, I am afraid I smell." "No," he said, "I smell; you stink."

ASYMMETRY OF THE NASAL CHAMBERS.—Dr. HARRISON ALLEN, of Philadelphia, drew attention to the existence of this condition in some cases, and exhibited the skull of an idiot who was an example thereof. Asymmetry of the corresponding parietal bone existed in many of the cases.

ON THE RESULTS OF THE TREATMENT OF NASO-PHARYNGEAL FIBROMA, WITH DEMONSTRATION OF SUCCESSFUL CASES, TOGETHER WITH A TABLE OF SEVENTY-FOUR OPERATIONS BY DIFFERENT SURGEONS.—This paper was read by Dr. RUFUS P. LINCOLN, of New York. He believed that there was a method for the removal of

these tumors which could be more safely employed than that which was usually adopted by the general surgeon. He did not, however, advocate the method which he had employed with such excellent results to the exclusion of all other methods. A loop of platinum wire was passed through the nostril behind the tumor, the patient was etherized, the battery was attached, the pedicle severed, and the tumor removed through the mouth. The following was the tabulated list:

The operations were performed upon fifty-eight patients, including three of his own cases. There were 74 operations in all, and were tabulated as follows: Of the patients, 46 were males, 8 were females, and in 4 the sex was not stated. Age: Under 8 years of age, 2; between 14 and 23, 31; between 23 and 30, 4; between 33 and 42, 6; between 43 and 52, 5; one patient was 54 years of age, another 55, and the age was not stated in 8 cases.

Of the operations involving section of the bones of the face, there were 39 performed upon 28 patients. The number of recurrences which took place within a year was 14. The number of cases reported under observation without recurrence, 4. The number of cases in which there was no record subsequent to the operation, 13. The number of deaths as a result or attributable to the operation itself, 8. In 3 other cases the operation nearly proved fatal.

Removal by knife, scissors, forceps, etc., 7 operations performed upon 7 patients. Number of recurrences, none. Number of cases reported under observation one year or more subsequent to the operation without recurrence, 6. Number of cases in which there was no record subsequent to the operation, 5.

Removal by the écraseur-ligature, 12 operations performed upon 11 patients. Recurrences within one year, 6. Under observation for one year or more without recurrence, 4. No record subsequent to the operation, 2.

Treatment by injections, cauterization, etc. Number of cases treated, 2. Recurrence within one year, 1. Without record subsequent to the operation, 1.

Removal by electrolysis in 3 cases. Recurrence within one year, 1. No record after operation, 2.

Removal by the galvanic cautery écraseur, 11 operations performed upon 10 patients. Number of recurrences within one year, 3. Under observation for one year or more without recurrence, 6. No record subsequent to the operation, 2. Fatal cases, none.

Dr. JARVIS referred to a case in which he removed a very large myxo-fibroma, which partially occupied the right and completely occluded the left nasal passage, using his wire snare. No hemorrhage occurred. Not a vestige of the tumor was to be seen four months after the operation. He also exhibited a new nasal speculum.

Dr. A. H. SMITH had removed a fibromata from the nasal passages by means of the snare, as had also Dr. Seiler.

Dr. INGALLS referred to cases successfully treated with the galvanic cautery écraseur.

Dr. BOSWORTH hoped that the tabulated list presented by Dr. Lincoln would have the effect to lead general surgeons to abandon the horrible and dangerous operation by removal of the superior maxilla.

Dr. E. HOLDEN, of Newark, presented a CARBON ILLUMINATOR FOR EXAMINATION OF THE THROAT AND LARYNX, being an adaptation of Edison's illuminator.

Third Day—Morning Session.

A CASE OF THYROIDOMY FOR MORBID GROWTH, WITH SUBSEQUENT DEVELOPMENT OF EPITHELIOMA IN THE CUTANEOUS CICATRIX, BUT WITHOUT INVOLVEMENT OF THE INTERIOR OF THE LA-

RYNX.—Dr. J. SOLIS COHEN, of Philadelphia, read a paper with this title. The patient, a lawyer, sixty-three years of age, had been unable to pursue his professional avocation for two years on account of loss of voice. Thyrotomy was performed and a papilloma was removed. Subsequently Dr. Agnew removed an epitheliomatous growth which developed over the right wing of the thyroid cartilage, but not connected with the cartilage; and a second epitheliomatous growth, developing upon the left wing of the thyroid cartilage, was removed by Dr. Cohen nearly three months later. The patient did well for some time afterward, but finally died with symptoms of constitutional cachexia. The epitheliomatous disease was believed to have been due to irritation.

EXPERIMENTAL RESEARCHES ON THE TENSION OF THE VOCAL BANDS.—This paper was read by Dr. F. H. HOOPER, of Boston, by whom it was prepared in conjunction with Professor BOWDITCH, of the Harvard Medical School. The experiments were divided into two series: First, those which demonstrated that the action of the crico-thyroid muscle was to draw the cricoid cartilage upward on the thyroid; and, second, to determine the effect of the air-blast upon the tension of the vocal bands. The experiments were ninety-two in number, and were made upon nine dogs. In the first series, the animal was etherized, the larynx exposed, the branch of the laryngeal nerve supplying the crico-thyroid muscles stimulated, and the action upon the cartilages recorded by sphygmographic tracings. It was determined that the cricoid cartilage was the most movable part of the laryngo-tracheal tract; that the thyro-cricoid muscle should be described as arising from the thyroid cartilage and inserted into and giving motion to the cricoid cartilage. The second series of experiments established the fact that the air-blast was a direct and important longitudinal tensor of the vocal bands.

The President said that it would be impossible to estimate the value and the scope of a paper giving the results of so laborious and profound experimental research as did the one which had just been read, or to discuss it intelligently, without time for its careful study.

AURAL COMPLICATIONS OF INFLAMMATORY CONDITIONS OF THE NOSE AND THROAT.—Dr. BEVERLEY ROBINSON, of New York, read a paper on this subject, pointing out the symptoms which indicated the development of the aural complication in many diseases in which the nose and throat became affected. He believed that, in the eruptive fevers in which inflammation of the middle ear so frequently developed, the aural affection was due rather to the nature of the disease than to extension of inflammation from the throat, although when the latter was present the otitis was more likely to occur. The subject was divided into aural complications accompanying nasal and throat disease of an inflammatory character, first, of an acute, and second, of a chronic kind.

Dr. MACKENZIE, of Baltimore, had excited redness of the drum membrane by irritation of the sensitive point in the nasal passages before mentioned, and he believed that otitis media was sometimes of reflex origin, due to disease of the nose.

TWO POINTS IN THE ANATOMY OF THE LACUNÆ TONSILLARUM was the title of a paper read by Dr. D. BRYSON DELAVAN, of New York. The increased superficial area of the mucous membrane arising from the anatomical formation of the lacunæ, and its great attenuation in the depressions, constituted important factors in the pathology and treatment of affections of the tonsils.

Afternoon Session.

THE VALUE OF POST-LARYNGEAL PAPILLOMATA AS A MEANS OF DIAGNOSIS IN TUBERCULAR DISEASE.—The paper was read by Dr. G. W. MAJOR, of Montreal, who stated that, where a vel-

vety appearance of the parts referred to only had been reached, cure was sometimes effected; but, where the condition showed filamentous growths, none of the patients recovered. The cases referred to were those in which there was a family history of phthisis. The conditions mentioned, however, also, might exist in non-phthisical subjects.

A CASE OF ENORMOUS TUMOR REMOVED FROM THE GLOSSO-PHARYNGEAL SINUS, WITH REMARKS.—Dr. E. C. MORGAN, of Washington, related a case in which the tumor was of about the size of a walnut, and was removed with the finger, the pedicle being comparatively small. Microscopical examination showed that it was a myxo-sarcoma. The bibliography of the removal of tumors of a similar nature in this situation was given.

In the discussion which followed, reference was made to the value of the finger-nail as an instrument with which to remove tumors of the naso-pharyngeal space. It had been used successfully in several cases.

A CASE OF SUDDEN DEATH OCCURRING AFTER TRACHEOTOMY, WITH REMARKS.—This was the title of a paper read by Dr. MORRIS J. ASCH, of New York. In the case operated upon, the man did very well for some days, and was relieved of the symptoms of suffocation due to ulceration of the vocal cords. He suddenly died, apparently without cause, a few days after the operation. The post-mortem examination revealed no condition which would account for death. Dr. Asch believed that the fatal result must be accounted for on the theory of inhibition, spoken of by Brown-Séquard. He regarded tracheotomy as a very difficult operation, and also a very dangerous one, and believed that it should not be resorted to except for the relief of urgent symptoms.

ON ADHESION OF THE VELUM TO THE WALLS OF THE PHARYNX.—A paper with this title was read by Dr. A. H. SMITH, of New York. The condition was due almost or quite invariably to syphilitic ulceration, involving the wall of the pharynx and of the posterior surface of the velum, causing their adhesion by cicatrization. The occlusion of the nasal passages was more or less complete, and sometimes demanded an operation to admit of the passage of air through the nose, and the escape of offensive accumulations from the nasal mucous membrane. If a sinus existed, a cutting operation might not be necessary, dilatation proving effectual. Patients upon whom operations had been performed were presented.

The incoming President, Dr. FRANK H. BOSWORTH, was conducted to the chair, and spoke of the large attendance and the excellent work done at the present meeting, and said that he could not hope at the end of the year to leave the society in a more prosperous condition than that in which it had been left by the efforts of their worthy outgoing President, Dr. Lefferts.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

A REGULAR meeting was held February 8, 1883, Dr. JAMES TYSON, President, in the chair.

THE MORPHOLOGY OF PULMONARY PHTHISIS, by Dr. EDWARD T. BRUNN.—I have been requested by the committee of arrangement to present some considerations bearing upon the pathological anatomy of phthisis, as the basis of a discussion of the subject before the society. The etiology of phthisis is very properly exciting careful attention at present, but the subject is in a far too unsettled condition to permit even a useful discussion. I shall not, therefore, allude to it, and I feel that I must offer an apology for the triteness of the subject-matter of my paper; but I was informed that it was designed to have a series of discussions upon familiar pathological conditions. With this understanding, my scruples have been overcome. A consideration of special interest seems to me to be connected with the

morphology of primary tubercle. In certain individuals, owing to inherited tendency, or particularly unfavorable surroundings, recovery after bronchitis due to cold is retarded, or a susceptibility to a new bronchitis is increased. In either case lingering catarrh, in the majority of instances, is the inception of the series of pathological processes known as phthisis pulmonalis. Two microscopical appearances nearly identical occur, but they differ materially in their microscopic anatomy. Certain so-called miliary tubercles are frequently composed only of the inflammatory products of connective tissue, without the characteristic true tubercular arrangement. The word miliary expresses their appearance, but the inflammatory products may be so arranged as to represent true tubercle, pseudo-tubercle, or a diffuse inflammation. This tubercle, or pseudo-tubercle, is constant in the different forms of phthisis in the adult, except in the instance of pure interstitial pneumonia. Frequently the amount of tubercle tissue in the lungs is so great as to form the principal part of the process, although complicating inflammatory cheesy products are also present.

CLASSIFICATION OF PHTHISIS.—The term tubercular peri-bronchitis is probably the best for the earliest stage of phthisis, and sometimes is the best designation for the process all the way through. The appearance of the peri-bronchial tissues resembles berries on a stalk. The formation extends along the bronchi, spreading from acinus to acinus until the trunk is reached, and is also distributed in the sheaths of vessels and lymphatics. True tubercle may penetrate a bronchus and involve the lining membrane, and a true tuberculous ulcer may form the basis of an extensive associated bronchitis. Aside from this, these infiltrations excite interlobular connective-tissue growth, and subsequently the walls of the vesicles become thickened, and some vesicular catarrh ensues which may occlude a lobule. Thus, the three divisions of the pulmonary tissue share in the pathological process of early phthisis. The cause of more than nineteen twentieths of vesicular consolidation is the result of a process of desquamative pneumonia. This term is used to describe the diffuse inflammation which may accompany the former processes, and which, more than the other changes, paves the way for the disintegration of the lung. In this process the peripheral epithelial cells of the bronchi are proliferated and shed, thus filling the bronchi and infundibula, while the surrounding connective tissue becomes infiltrated with cells. In children this process is a common one, on account of the greater cellular activity in these subjects. In the desquamative catarrhal pneumonias of early life the process differs from the desquamative pneumonias of adults in that the air-cells only are filled, and there is little or no change in the intervascular tissue. Hence it is that recovery is so much more frequent in children than in adults. This process of desquamative catarrh is the basis of those cases of acutely developed phthisis which follow croupous or catarrhal pneumonia, and which has been called acute catarrhal phthisis or galloping consumption—sometimes pneumonic phthisis. When the pathological process just described is less rapid, the result which follows has been classed by some as acute caseous pneumonia. When the changes are still more slowly developed, it is synonymous with the chronic catarrhal pneumonia. The relative development, then, of these processes known as phthisis in the three divisions of the pulmonary tissues—the bronchial, the interlobular, and the vesicular—is dominated by the activity of the inflammatory process; peri-bronchitis with consecutive changes occurring in the latent forms, desquamative pneumonia in the more acute forms, while a process, presently to be alluded to—interstitial phthisis—occurs as a very slowly developed change. In many of these cases, when the destruction of the lung is very rapid, the tubercular deposition, true or false, occurs in early

stages, but is marked in the latter by the development of the secondary, inflammatory, desquamative, pneumonic processes. The situation at which phthisis is developed is probably most frequently the apex. The forces of expiration presumably are least efficient at this site, and the lungs are less entirely freed from mucus. The circulation also is less than at the roots, and the products of inflammation are, therefore, more dry. The roots of the lungs, however, in a large minority of cases, are primarily affected. This is especially true of cases in which the original processes of invasion are latent. I pause here to observe a clinical point of some interest—viz., that when the area of lung involved in the process of phthisis is distinctly limited, and does not shade off gradually into healthy lungs, my opinion is that a favorable result may be very possible. Certainly I have seen the process of phthisis arrested even when it had passed into the stage of cavity when the lesions were sharply defined. The localization of a lesion, other things being equal, is a point of favorable prognosis. Another topic of interest is the share taken by pleurisy in the development of phthisis. A specimen already exhibited before the society is again shown to-night. It was taken from a colored man, seventy years old, with a family history free from the taint of pulmonary disease. He was tapped five times for the relief of hydrothorax due to heart-failure. Each paracentesis was followed by an exacerbation of pleurisy. Nine months after the first operation death occurred from an increase of hydrothorax. The autopsy disclosed general miliary tuberculosis of the pleura and secondary deposits in the viscera. Throughout the parenchyma of the lung adjacent to the pleura there was a copious deposit of tubercle, but the other parts of the lungs were normal. Another specimen exhibits the same tendency—viz., general pleurisy with phthisis and cheesy deposit in the pulmonary parenchyma, with cavities. The deposits are most abundant near the pleural surface of the lung, the deeper parts giving evidence of a more recent formation. These specimens show that pleurisy may give origin to a tuberculous inflammation. But, while this is true, it is conceded by all that dry pleurisy is a frequent secondary lesion in the progress of pulmonary tuberculosis. Pleurisy is, however, in many cases very conservative, since by the thickening and adhesion of the pleural surfaces the ulceration of the walls of superficial cavities is arrested, and pneumothorax is prevented.

Interstitial Phthisis, or Cirrhosis, is a process in which true or pseudo-tubercle may or may not be associated. The pulmonary tissues are traversed by narrow bands of connective tissue which may gradually compress it more and more, finally converting it into dense fibrous masses. The color of the lung is apt to be slaty and dark. However, in some cases of interstitial phthisis, patches of the peri-bronchial and desquamative pneumonia may be found with cheesy degeneration. Interstitial formation is an important part of the process by which cavities are inclosed and sometimes cicatrized.

Distribution.—Interstitial phthisis, if consecutive to bronchitis, is usually bilateral, affecting the upper lobes, although as a unilateral affection it is not infrequent.

Syphilitic Phthisis.—It is of interest to note in this connection that the early lesions of syphilitic phthisis, so called, are evoked very often by bronchial catarrhal inflammation, which predisposes to structural changes. In these cases there is a principal interstitial fibro-nuclear growth commencing in the alveolar wall and concentrically arranged around the smallest bronchi and pulmonary vessels. Wagner maintains that the alveolar wall is implicated as commonly in syphilis as in ordinary phthisis. Bronchial narrowing occurs in these cases by the pressure of the new growth which develops along their lumen. Bronchial occlusion may occur from this new forma-

tion, but it is also caused by the enlarged bronchial glands, one of the effects of syphilis. By this means serious mischief in the lungs may be developed, in kind proportioned to the degree of obstruction, such as atelectasis, emphysema, and certain forms of pneumonia. Green and Virchow suggest that the origin of syphilitic diseases of the lung is distinctive in this respect; that while in ordinary phthisis the fibroid is secondary or co-equal in its development with changes in the alveoli and alveolar wall, in syphilis there are primarily principal interstitial changes. Later, when entire vesicular consolidation and breaking down occurs, the process is similar to ordinary phthisis, and indistinguishable from it. The vascularity of the new growth of connective tissue is also claimed to be a distinctive characteristic of the inflammatory proliferation due to syphilis. But we must remember, in any discussion of early syphilitic lung disease, that the one special and characteristic lesion of syphilis is the change in the intima of the blood-vessels. This has not yet been demonstrated in the lung, but merely general thickening of the external coat of the vessels. In the effect of interstitial processes upon the bronchial tubes, the syphilitic differs from the non-specific disease. The tough, contracting fibrous tissue which radiates through the lung draws together the bronchial tubes, and deforms, by narrowing or flattening them, possibly even to obliteration. On the contrary, in the forms of non-syphilitic fibroid phthisis the bronchial tubes are widened. The process proceeds in syphilis from the hilus into the interior of the lung, following the track of the bronchial radicals and the bronchial arteries. The lesions also occur on the surface, near the visceral pleura, where there is also more connective tissue. Gummata occur as a later process. Time will not allow me to allude to these as I should like. A demonstration of the pathology of phthisis would be incomplete without including some cases of true miliary tuberculosis. This process may be primary in the lungs, or secondary as a part of the general infiltration of the serous and mucous membranes, the lymphatic glands, and the viscera. This form of tubercle is characteristically recognizable only in the miliary stage. Its appearance as a number of small, hard, translucent nodules is too familiar to need description. A specimen upon the table illustrates an extensive lymphangitis of the pulmonary pleura forming a network over the pleura. The process microscopically shows adenoid tissue in nodular form. Similar cases were described before the London Pathological Society in 1880.

Enlargement of the Bronchial Glands.—Another important part of the phthisical process is the enlargement of the bronchial glands. They present a firm, pigmented character, and the connective tissue is usually infiltrated. I have observed in many cases, in individuals suffering from temporary catarrhal conditions of the bronchial mucous membrane, especially when there is a family history of inherited phthisis, but particularly in distinctly scrofulous persons, a set of symptoms referable to enlargement of these glands. These symptoms consist chiefly in an alteration in the rhythm of the breathing, presumably from pneumogastric irritation, in apparent inability to fill the chest with air, and a sense of suffocation is complained of. Added to these there is *pain* in the back to the right or left of the second dorsal vertebra. Further detail of the clinical ensemble would carry one away from the pathology of the subject. When the enlargement of the bronchial glands is excessive it may occasion severe mediastinal pressure, and pain becomes an important clinical symptom, and is of the sort occasioned by mediastinal growth generally. To detect this enlargement during life, Guéneau de Mussy has suggested percussion over the spinous processes of the cervical vertebrae in the course of the trachea. Following this line in healthy subjects, a distinct tubular sound is elicited by percussion down to the

point of bifurcation of the trachea at the level of and opposite the fifth, and downward we get the lower pitched and pulmonary resonance. When the tracheal or bronchial glands are enlarged, the tubular sound over the upper dorsal vertebrae is replaced by dullness, which may contrast sharply above with the tracheal and below with the vesicular resonance. The result of bronchial pressure upon the pulmonary tissues is best marked when the processes of phthisis are not too extensive, also in interstitial phthisis, or in cases where there is marked bronchitic complication. In these cases the lumen of the bronchi is seriously diminished and vesicular air-supply is interfered with. Consequently, emphysema, with or without asthma, atelectasis, or a very intractable bronchitis, may occur. I will not describe the morbid process of phthisis in detail. The involvement of an entire lung is simply the filling up of the parenchyma with peribronchial product or with the results of the desquamative, pneumonic, or interstitial process. And as one or the other of these predominates, so do we have peribronchial, fibroid, or catarrhal phthisis. Another interesting, although not demonstrable, incident in the pathology of phthisis is hæmorrhage. Bleeding from the lungs occurs both early and late in the history of cases. The late hæmorrhage is easy to explain, being nearly always due to ulceration of the blood-vessel walls. The cause of early hæmorrhage is less simple; it is possible that in cases of phthisis there may be malnutrition or fatty degeneration of the blood-vessel walls, rendering rupture under conditions of increased arterial tension in the lungs an easy circumstance. It may also be the result of tubercular infiltration of the muscular walls which is followed by rupture of the blood-vessels.

Cavities in Phthisis are the result of several processes. They occur by (a) a slow or rapid process of fatty degeneration, followed by ulceration; (b) as the result of chronic bronchitis and softening of bronchial tissue, with subsequent yielding to traction from without—for instance, in broncho-pneumonia, or fibroid phthisis; (c) abscesses as a sequence of acute lobar pneumonia, following hepatization or purulent infiltration; (d) as the direct result of gangrene, itself the immediate consequence of wounds of the lung or blood poisoning, or of emboli. Local gangrene, on a small scale, occurs sometimes around cavities in the lungs, or in the bronchial tubes, and may give rise to temporary factor of breath, but is not likely to lead to fallacious inferences, chiefly because of its temporary character and the absence of permanent concomitant symptoms. It naturally follows that there are two locations for vomicae—the pulmonary and bronchial tissues. Specimens illustrating the various forms of cavities are upon the table. The limits of a paper designed to open a discussion on phthisis will not permit me to dwell upon the bearing of these pathological changes upon physical diagnosis. I therefore will close with a brief *résumé* of the general clinical symptoms which define the diagnosis of the various sorts of cavities.

Phthisical Cavities commonly are situated in one or both lungs, and are indicated as a development in a train of symptoms which include as prominent features gradual emaciation; persistent loss of weight by reason of mal-assimilation of food; more or less frequent hæmorrhage and hectic, frequent pulse; hacking, intermittent cough; nummular sputum, expectorated in varying amounts throughout the twenty-four hours, and not periodically, as in bronchial dilatations, nor inaugurated by a gush of pus and mucus, as in abscess.

Cavities of the Nature of Abscesses.—The pathology of these cavities, with its coincident clinical history, is not that of phthisis. The history of these cavities is either recovery by contraction (especially after wounds), or more frequently the abscess grows larger and larger until the entire lung may be destroyed, in this respect resembling phthisical cavities. Where

death occurs, it is by exhaustion and hectic; where recovery takes place, it is by free opening, externally or internally, and evacuation of the contents. At times the small amount of constitutional disturbance, slight degree of emaciation, good pulse, easy breathing, slight cough, and healthy complexion are in noticeable contrast with the physical signs. Cavities of the nature just described are mostly located in the base of the lungs.

Cavities due to Bronchial Dilatation.—Frequently for years the general health is almost unimpaired, and it is never so proportionately to the degree indicated by the physical signs. There is no hæmorrhage nor night sweats, and emaciation is not a pronounced symptom. The same physical signs persist for months or years unchanged, contrary to the history of most phthisical cavities, which continually alter with the advancing malady. The expectoration of bronchial dilatation is more abundant, fluid, and purulent than in catarrhal phthisis, and is usually brought up in the morning or evening by the cupful. It is not a constant spitting of nummular sputa, as in true consumption. In chronic cases the expectoration may become so fetid as to generate suspicions of gangrene; the cough is harassing, but is often relieved if the bronchial cavity is thoroughly emptied.

Dr. MUSSEY said that little could be added to this admirable and concise, yet exhaustive, *résumé* of Dr. Bruen's on the morphology of phthisis. The limited experience that he had had in the study of the histology of phthisis had convinced him that in the microscopical structure of the lesions there is but little difference noteworthy in the primary changes. We had one school teaching that inflammation, another that tubercle, was the primary element. He could not but agree with the author of the paper in the statement that the disease varied histologically with the variance in the intensity of one of these elements. In both we had epithelial proliferation and accumulation, changes in the vascular and lymphatic tissues (tubercle), and increase in the interlobular connective tissue. So intimately was the evolution of each of these processes connected that a classification like that of Greene ("Lancet," 1882) seemed most proper: (a) Consolidation intra-alveolar. (b) Consolidation involving mainly alveolar walls. (c) Consolidation consisting largely of intra-lobular connective tissue. Without absolute committal either way, and yet in the line of exact truth, the distinction thus given seemed to cover the entire histological ground. Dr. Mussey had had abundant opportunity for the study of the clinical aspect of phthisis, and, although an arbitrary histological distinction of its varieties could not be made, it was of the utmost importance as influencing treatment, and hence the prognosis of the case, to have a distinct and definite idea of the clinical varieties. The importance of the subject would be sufficient apology for the clinical remarks. Ante- and post-mortem observation had led him to adopt the following classification, as convenient, systematic, and embodying the various phases of the disease:

A. Acute. 1. Catarrhal pneumonia. 2. Pneumonic or caseous phthisis. 3. Pulmonary tuberculosis. 4. Miliary tuberculosis.

B. 1. Catarrhal pneumonia; tubercle might be secondary. 2. Tuberculosis. 3. Interstitial or fibroid phthisis; tubercle might be secondary.

He said that it was scarcely fair or proper to call acute catarrhal pneumonia a kind of phthisis, as it was only related as a possible primary factor. So seldom was it recognized, and so baneful were the results of non-recognition, and hence inactive and inadequate treatment, that it was important to show its relation. It would be observed that catarrh and tubercle were distinguished, and so, for convenience and contrast, we might

term the kinds "catarrhal" and "tubercular." Perhaps a clew to the pathology of phthisis might be found in defining the characteristics of each. In the first place, there was a marked difference in the predisposing causes of the disease—hereditary and diathetic conditions. Thus, tubercular phthisis was markedly hereditary, catarrhal was not; the tubercular was associated with the tubercular diathesis and a phthinoid chest; the catarrhal, in some, with the scrofulous diathesis and a perfect chest. Then the mode of onset differed greatly. In the former the general symptoms were more marked, the pulmonary symptoms in abeyance; in the latter, the pulmonary symptoms were more marked, the general slight. Emaciation, loss of appetite, and dyspepsia preceded or accompanied the development of the former; they did not occur until late in the latter. Amenorrhœa and changes in the voice also occurred early in tubercular phthisis. In tubercular phthisis, hæmorrhage occurred more frequently and earlier than in catarrhal. In tubercular phthisis, dyspnoea was a more marked and early symptom, and was out of proportion to the physical signs. Debility was more marked and more readily induced in tubercular phthisis. The temperature range was not so high early, and did not have the long daily sweeps in the late stages in tubercular as in catarrhal phthisis. With a doubtful mask, it seemed that pleurisy and chest-pain were more common and constant in the tubercular than in the catarrhal form. The physical signs were bilateral and not pronounced in the tubercular form; they were unilateral and pronounced in the catarrhal form. The progress of the tubercular form was rapidly and progressively downward; of the catarrhal, slow and in spurts. Tubercular phthisis was contagious and auto-infective. Over and over again did cases present themselves at the University Hospital and Dispensary with just such definite and broad distinctions, which distinctions should determine the line of treatment to be adopted, the catarrhal form requiring a more active local and general antiphtisic treatment. It was not to be forgotten that the cases were not always, he might say generally, so easily distinguished, while the picture did not apply to acute miliary tuberculosis or fibroid phthisis. In a previous discussion on phthisis, Dr. Mussey had held that acute primary plastic pleurisy did not occur save in a tubercular subject, and hence was secondary to that diathesis. That statement was possibly too broad, and it should be that frequently recurring acute pleurisies occurred only in the tubercularly diathetic, and were antecedent to the development of phthisis. The recognition of exocardial and subclavian murmurs led one to say that persons having such sounds were threatened with phthisis.

Dr. ESKRIDGE said that he had been much interested in Dr. Bruen's remarks, in most of which he concurred. As to pleurisy antedating phthisis, it was an old view, which had lately been revived. He had been struck with the frequency of chest-pains preceding phthisis. "In over seven hundred cases of which he had notes, this symptom was noted in more than two thirds. This pain might be on the opposite side to that of the affected lung. Interstitial phthisis was not always a chronic affection, Dr. Barlow and others having reported cases which proved fatal in six months. Hæmorrhage, in his experience, was a very common symptom in this variety of phthisis. Dr. Eskridge called attention to the fact that cardiac valvular diseases, especially mitral regurgitation attended by venous congestions and coming on after birth, were rarely associated with phthisis, while congenital deformities of the heart attended by venous stasis, etc., were followed, according to some eminent authorities, in nine tenths of the cases, by tuberculosis of the lungs.

Dr. SHAKESPEARE said that one point made by the lecturer had especially struck him as being opposed to his own experience—viz., that the part of the lung attacked earliest was gen-

erally the root. He had usually found the consolidation at the periphery of the lobe, often forming, as it were, a shell of solid lung perhaps an inch thick, while the central or deep portions would be either not at all or but little affected. This peripheral consolidation seemed to have no particular relation to initial pleuritis, for the consolidations were quite frequently met with in cases almost free from pleuritis and old adhesions. He had also very often noticed, at autopsies after death from intercurrent diseases, wedge-shaped patches of solidified lung tissue having the base at the periphery of the organ and a slightly raised surface, much like infarcts, and containing miliary tubercle, while the intervening pulmonary tissue was normal.

Dr. FORMAD asked Dr. Bruen what he considered was the difference in the pathology of acute and chronic phthisis. Also, on which side the disease most commonly occurred. Dr. Formad also desired put on record some new observations on the histology of phthisis made by W. H. Mercer in the Pathological Laboratory of the University of Pennsylvania, which he narrated as follows: That acute phthisis (all fatal cases) was invariably complicated with croupous pneumonia, which conditioned the lethal termination; that the lining of the bronchioles and the endothelium of the blood-vessels played a very active part in the formation of organized tubercle granulations, filling and widely distending the lumina in both instances. The existing observations on this point, so far as he remembered, referred only to blood-vessels, and then merely to cheesy, broken-down material obliterating vessels, or occasionally to the formation of giant-cells, or to something which in transverse section simulated a giant-cell. Mr. Mercer states that the obliteration of bronchioles by living, organized granulation-tissue was the most common starting-point for pulmonary tubercle granulations, and formed the greater bulk of the latter. He also found that the exudate within the air-vesicles in acute phthisis was capable of undergoing complete organization, and that a group of such blocked-up air vesicles with organized exudate was usually called (erroneously) a miliary tubercle, the outlines of the air-vesicles being mistaken for submiliary tubercles. Mr. Mercer had failed to find a single true miliary tubercle in a large number of thoroughly studied cases of phthisis, and agreed with those who regarded miliary tubercle nodes as secondary products only. Dr. Formad desired distinctly to state that Mr. Mercer's observations were made on and applied only to the lungs.

Dr. TYSON was interested to note how much histological investigation had contributed to our knowledge of the nature of these important processes under discussion; and, while he was ready to admit that we owed much to experimental pathology, he felt that our present more correct notions were the result of microscopic studies of the human tubercular lung. The point to be insisted upon was, that all these processes were tubercular and all were inflammatory, the catarrh of the lung and tubercle granulations being in all cases the initial lesion, whence it extended peripherally by desquamative catarrhal pneumonia or centripetally by a tuberculous peribronchitis, the former furnishing the rapid and the latter the slow forms of phthisis. That pleurisy was often the initial lesion of tuberculosis he thought had long been acknowledged.

Dr. SHAKEPEARE said that the observations reported by Dr. Formad for his pupil reflected great credit upon both, and was another testimony of the value of the work done in the pathological laboratory of the University, but at least two of the announcements, for which novelty and originality were claimed, had been forestalled years ago by other observers. He had particular reference to the organization of the products within the alveoli of the lung, and the announcement that the walls of the minute blood-vessels, by a proliferating endoarteritis and periarteritis, formed the miliary tubercle. The former was

not only recognized and described in Green's "Hand-book of Pathology," but was also most beautifully illustrated. The latter had been repeatedly observed and published, sometimes with illustrations. This origin of tubercle was distinctly referred to in the text-books of Wagner and Cornil and Ranvier. All these books were in the hands of the University students.

Dr. FORMAD said that existing observations on this point, so far as he remembered, referred only to blood-vessels, and then merely to cheesy, broken-down material obliterating the vessels, or occasionally to the formation of a giant-cell, or to something which, in transverse section, simulated a giant-cell.

In closing the debate upon the subject, Dr. BRUEN said that he had coincided with Dr. Tyson in the opinion that phthisis was rarely associated with heart-disease. In mitral regurgitation there was often, indeed, a thickening of the pulmonary substance allied to the indurative changes in the other organs from like causes. Advanced fibroid disease, with cavities, as shown in one of the specimens exhibited by him through the kindness of Dr. Hinsdale, he had not met with heretofore.

Dr. FORMAD's query as to the relative frequency of phthisis upon the right or left side he felt must be answered by the statement that one side was as liable to disease as the other, while, probably in a small majority, the right side was most frequently involved. He thought that the peripheral portion of the apices anteriorly was the most common starting-point, where there was much desquamative pneumonia and rapid phthisis, while the roots posteriorly were primarily attacked in the more slowly developed forms of broncho-pneumonic phthisis. The roots of the lungs were the seats of the latent phthisis developed as the sequential lesion of croupous pneumonia.

Dr. BRUEN dissented from the view that croupous pneumonia was a frequent cause of death in phthisis. He believed that in the rapid, as well as in the more latent form of phthisis, death was preceded and hastened by a development of the tubercular nodular tissue to which allusion had already been made. This tissue completely filled up and choked the acinous pulmonary structure, causing dyspnoea, etc.

C. B. NANCREDE, M.D.,
Recorder.

Letters to the Editor.

THE MARINE-HOSPITAL SERVICE AND ITS DETRACTORS.

WASHINGTON, May 21, 1883.

To the Editor of the New York Medical Journal:

As a matter of justice to the Marine-Hospital service and to myself, will you kindly allow me to reach the profession through you by publishing a reply to the following scandalous charges, which have been repeatedly made by certain of the brethren who have a grievance:

THE INSINUATIONS. (SAMPLES.)

We think that Dr. Hamilton, in publicly comparing the professional and financial management of hospital patients in the two services, unreasonably washes-linen-in-public, and makes comparisons which are unequalled for and unprofessional.

To a civilian, accustomed to the amenities of professional life, it seems very strange that when a doctor becomes a politician he should lose all remembrance of the only under which he first drew his professional breath.—*Medical Times*, March 24, 1883.

THE FACTS.

Dr. Hamilton simply replied to an assertion that it would be more economical to treat merchant sailors in naval hospitals. He nowhere attacked the professional character of the Medical Corps, many of whom he numbers among his personal friends, and for whom as a body of professional men, he entertains the highest respect.

In the Report of the Supervising Surgeon-General of the Marine Hospital it is stated that the hospital at New Orleans had been offered for sale at thirty thousand dollars, but that, no sale having been made, the service had sustained the loss of the money paid for advertising.

The facts seem to be that this hospital, which had cost originally five hundred and ninety thousand dollars, and had had spent on it one hundred and fifty thousand dollars, was offered for sale, with the result of the highest bid being nineteen thousand dollars. All this the honest, straightforward Surgeon-General of Marines did not deem of any interest to the general public, although he could weep over the pennies lost in the besmirchment of printer's ink. No wonder his virtuous indignation had to find vent upon the bad management of the medical affairs of the navy. Seven hundred and twenty-one thousand dollars taken from the hard earnings of sailors, to be wasted in one hospital, through incompetency, or something worse!

Again, we are told—but not in the report—that at Cincinnati a marine hospital was obtained at the cost of two hundred and thirty thousand dollars, and sold for seventy-five thousand dollars—a hundred and fifty-five thousand dollars more gone! How many more of these hospital operations have disgraced the Marine-Hospital service we do not know, as we have no official facts to enlighten us; but those given in this editorial are vouched for as accurate by high authority. We should be most happy to publish an official denial of them. Of course, no one has made money by these operations. No American politician ever did make money. Congress certainly ought, however, to insist on having a complete honest statement, so brief and clear that it could be read and understood by every one, of all the doings and the losses of this branch of the service; for, at present, its stupendous political cupidity and activity seem equaled only by the mystery of its mismanagement.—*Philadelphia Medical Times*, May 5, 1883.

For an attack on the late Surgeon-General (Woodworth), see the *Philadelphia Medical Times*, March 15, 1879.

Concerning similar attacks upon himself, Senator Sherman once pointedly said that to certain slanderers "the jail would be a refuge, and a libel suit a paying advertisement." If Dr. H. C. Wood thinks there is anything in this quotation personal to himself, he is welcome to make the application. I, however, must thank Dr. Wood for varying from his usual policy and practice by making his insinuations against myself while I am yet alive and able to speak in my defense. His bitter attack against my predecessor was written while that officer was on his deathbed, and was printed while the earth was fresh upon his coffin. And such is the would-be apostle of "the amenities of professional life!"

Very respectfully,

JOHN B. HAMILTON.

This New Orleans hospital was planned in 1855. It was never finished, and was used as barracks by troops of both armies at intervals during the late war. No person now in the Marine-Hospital service had anything to do with its plans or construction.

The Cincinnati hospital was commenced in 1856, completed in 1860, and was sold in 1866. Dr. John M. Woodworth was appointed to the office of Supervising Surgeon in 1871, was made Supervising Surgeon-General in 1875, and died in 1879. The writer was promoted in 1879, and no other persons have ever occupied the office, which was created in 1870, four years after the Cincinnati hospital was sold. Congress established the hospitals referred to from the public Treasury, not from the Hospital Fund; and, when the hospitals were sold, it was not in pursuance of any recommendation of this office, as the dates will easily show. In regard to the New Orleans hospital, Mr. Mullett reported long ago that it would cost more to repair the old, unfinished building than to build a new one, and Congress accordingly has ordered a new one built. Finally, if Dr. Wood is really desirous to find out the history of the service, he may do so by consulting Appletons' "Annual Cyclopaedia" for 1879, page 778; the "Annual Reports" for 1872, 1879, and especially, for a complete report on the New Orleans hospital, the "Annual Report" for 1880, page 179.

THE QUESTION OF THE CODES.

244 WEST 56TH ST., NEW YORK, May 22, 1883.

To the Editor of the *New York Medical Journal*:

SIR: This discussion of codes is becoming confused with side-issues. Really, the matter is in a nut-shell, and the test is simple enough, this one point settled, viz.: Is the new code calculated to give comfort and encouragement to homoeopathy; does the public take this view of the controversy?

No physician in possession of the proper spirit and teachings of his profession doubts that its principles are sound and its methods scientific, or that homoeopathy is utter nonsense and fraud, perverting the minds and corrupting the morals of the public (as all error does), and consuming the legitimate substance of medical progress and obstructing it in many other ways.

This is as certain to us as anything not mathematically demonstrable. If it deceives celebrated individuals, and is in popular favor, this proves that it is subtle and dangerous, but is not a reason for our public approval of it. It matters not what the State legislates concerning it. Knowing it to be false, we lift up our voices in condemnation until the public listens, is instructed, and legislates accordingly.

Is it illiberal to refuse to compound with the devil, or to depart from principles eternally right? Fraud can not be persecuted, nor is there anything in the liberal spirit of the times demanding a compromise with it, unless the spirit of commercial greed be the true spirit of the times, an insinuation indignantly repudiated by the advocates of the new code. Opportunism is one thing, liberalism quite another.

However much the attitude of the American Medical Association may affect us, it is of subordinate importance, and confuses the discussion. Its expression may serve as a safer guide to such as are disposed to settle the matter on authority alone, since it is less liable to have been influenced by local and personal considerations, is a more general expression, and conformable to long usage.

The old code certainly embodies a high ideal, and should be re-enacted unless a better substitute is offered. Or if the new code is to degrade this ideal and lower the tone of medical morals, granted that this ideal is too high to be appreciated by the general public in its present nebulous state of intellect and morals, hold it to plainer view, then; do not put it out of sight. If it be offering an indignity to those at the head of the profession to prescribe formulated rules to regulate their conduct, there is, at least, consolation for them in the reflection that laws are made to restrain, not the righteous, but the transgressors.

Whatever affects the moral attitude of the whole profession should be regulated by it, not left to the caprices of individuals, however heightened some of them may be. Without the admonishing presence of a formal code, it is to be feared that some might, in blindness or weakness, err from the straight and narrow path; or is it foginess that sees the path so straight and narrow as not to allow wide margins for way-side wanderings? We are not all shining lights in the profession; but all are human. It can do no harm to display the instruments of torture as warnings, to have means of discipline available; but it would scarcely appear the part of wisdom hastily to unarm and, too late, find ourselves defenseless.

When we have safely secured ourselves, and the general public is with us upon the moral level to which the old code leads, a constitutional preference having been acquired for that pure atmosphere; when error has become a psycho-physiological impossibility, those organic changes having become indelibly registered in the cephalic substance which may be supposed to result from an infinite series of uniformly virtuous thoughts and acts—under such circumstances a formulated code of ethics might seem superfluous to the utilitarian, but still to be sacredly treasured by the reverent and religious spirits.

Is it true that the old code is a dead letter? Vice is less dangerous committed secretly and in defiance of well-known laws than when the law permits its open indulgence; for then it ceases to be regarded as vice, and the virtuous become contaminated, and general moral decay ensues. Consulting with homoeopaths has generally been indulged in as a solitary vice, and, perhaps, with a sort of sneaking feeling of penal transgression, to be carefully concealed except from such as were known to sin likewise. It may not have been the intention of

its framers, but it seems plain that a fair construction of the new code will have a tendency to relieve distinguished gentlemen of all irksome restraints and permit free and easy association with homo-opaths and the like, without the fear of discipline ever being suggested even, however much the case might deserve it, and without there being too keenly felt any of the salutary and restraining influences which the old code was wont to inspire.

HOBART CHEESMAN, M. D.

Miscellany.

DIPHTHERIA SPREAD BY MILK.—"Toward the close of last year," says the "British Medical Journal," "an outbreak of diphtheria, presenting somewhat unusual characteristics, occurred at Devonport, and the Medical Department of the Local Government Board was compelled to yield to an urgent request from the Town Council that an investigation might be made into the circumstances attending the outbreak. Dr. H. Franklin Parsons was selected to undertake the inquiry, and his report contains many points of interest. In the first place, the outbreak differed from many others in its incidence upon persons of high social position. Members of the families and servants of professional men, and more especially of officers in the army and navy, including those in the highest command in both services, were the only class of people attacked. In but one single instance was a tradesman's family attacked, and no case is known to have occurred among the large working-class population. At the date of the inspection the number of known recent cases of the disease was thirty-one, of which five had proved fatal. The houses in which diphtheria occurred were of the better class, mostly in elevated and open situations; and there was nothing peculiar in their sanitary condition to account for the occurrence of the disease, nor, except in a very few instances, was there a known exposure to infection from a previous case. It was observed, however, that the greater number of persons affected with diphtheria obtained their milk from a particular dairy, upon which, in consequence, suspicion had fallen. Of the twenty-nine persons who were attacked in December, all were supplied from this dairy, with two exceptions, and one of these had certainly, and the other probably, had milk on some occasions from the same source. The dairy in question has a large trade in Devonport and Stoke, supplying about 256 houses, containing 347 families; and it is estimated that the customers who fetch milk from the shop would raise the number of families to nearly 500. There are other dairies doing a large business in the same place; but their customers, with some doubtful exceptions, entirely escaped. On visiting the farm whence the milk was obtained, Dr. Parsons found no abnormal conditions. It was noted, however, that a well had been closed at the suggestion of the local health officer, though it was explained that the water was only used for washing carts. Two men were employed in the dairy; but neither among them and their families, nor among lodgers in the same houses, could any recent sickness be discovered. The residents at the milk-shop—five adult persons—were also stated to have all been in good health; but next door a case of diphtheria had occurred early in December. In a narrow back yard behind the shop the milk-cans were washed with town water boiled in a small outhouse. From this outhouse the water-closet is divided by a partition; and, on pouring benzoline into the drain of the next house, in which a case of diphtheria had occurred, the smell was perceived in this water-closet. It seems not unreasonable to suppose that the infective matter may have gained access to the milk by the wiping out of the cans with cloths which had hung up in the narrow, close back yard, and had contracted impurities from the atmosphere. The small proportion of customers attacked, however, shows that any contamination of the milk by infective material could have only been partial and occasional in its occurrence. In view of the special incidence of the disease upon families of the well-to-do, and of the condition of the milk-shop premises, it is suggested whether the cream, standing as it did the longest time in the shop, might not have been especially the

vehicle by which the infection was conveyed; but Dr. Parsons met with no facts to corroborate this view. It is significant, however, that many of the persons attacked were constitutionally liable to sore throat. A chronic ulceration of the throat, a ragged tonsil, or an enlarged mucous follicle, would naturally afford more lodgment to infective material, and a fitter soil for its development, than a healthy and unbroken mucous membrane."

M. PASTEUR'S PENSION.—Steps are being taken to induce the French Parliament to increase M. Pasteur's pension from 12,000 fr. to 25,000 fr. annually, that allowance to revert to his wife and children at his death.

THE LUNATIC ASYLUM AT NEWARK.—The Grand Jury, whose intention to investigate the management of the county asylum at Newark we lately mentioned, is reported to have made a presentment to the effect that the institution is overcrowded, that different classes of patients are not sufficiently separated from each other, that the number of attendants is inadequate, that the nurses give drugs on their own responsibility, and in particular that a resident physician should be appointed.

THE LUNATIC ASYLUM AT NORTHAMPTON, MASS.—It is stated that the superintendent, Dr. Pliny Earle, will tender his resignation within a few months, and it is thought that the assistant superintendent, Dr. Edward B. Nims, will be promoted to the position thus vacated.

THE BLOCKLEY HOSPITAL ETHER.—At a recent meeting of the Hospital Committee of the Board of Guardians of the Blockley Almshouse, Philadelphia, a member of the medical staff called attention to the poor quality of the ether that was provided as an anæsthetic. Accordingly, the committee ordered that in the future only such ether should be procured as was specified by the physicians.

A SANITARY CONVENTION IN BALTIMORE.—At a recent meeting of the Maryland State Board of Health, on motion of Dr. Chancellor it was decided that hereafter sanitary conventions or meetings be held at least once a year, under the auspices of the board, in different parts of the State, with a view to promote a general interest in sanitary science; that the first meeting be held in Baltimore on the fourth Tuesday in October, 1883, and that a committee, consisting of the president and two members of the State board, the president and secretary of the city board, the president and secretary of the Medical and Surgical Faculty of Maryland, and five citizens, be appointed to consider the best means of holding the convention, that prominent sanitarians throughout the country be invited to take part in the convention, and that manufacturers and dealers in sanitary appliances be invited to forward their goods for exhibition at the meeting.

SMALL-POX IN PENNSYLVANIA AND MINNESOTA.—Press dispatches dated last Saturday stated that at that time there were thirteen prisoners sick with small-pox in the County Prison at Lancaster, Pa., and that there were twenty-five cases of the disease in St. Michaels, Minn., where several deaths from it had occurred.

SMALL-POX SPREAD AT A FUNERAL.—According to a newspaper report, a young woman recently died of small-pox in Cincinnati, where she was attending a music school. The case was diagnosed as one of purpura hemorrhagica, a burial permit was given on the strength of a death certificate to that effect, and the body was embalmed and sent to the young woman's home in Illinois, where it was exposed to view at a funeral, with the result of spreading small-pox in the neighborhood. It is added that two other pupils of the music school were afterward seized with the disease, and that the school building has been quarantined.

THE CONGRESSIONAL SANITATION FUND.—It is understood that the sum of one hundred thousand dollars appropriated by Congress for use in preventing the spread of epidemic diseases during the current year is to be intrusted by the President to the Marine-Hospital Service.

THE DANGER OF YELLOW FEVER FROM HAVANA.—The law requiring a sanitary inspection of vessels at Havana before they sail for this country expires to-day, and Congress has made no provision for a renewal of the requirement.

THE OREGON STATE MEDICAL SOCIETY.—The tenth annual meeting of the Oregon State Medical Society will be held at Portland, Wednesday, Thursday, and Friday, June 13, 14, and 15, 1883, commencing at 2 P. M. The following papers will be read: Antiseptic Surgery, by H. C. Wilson, M. D.; Chronic Nasal Catarrh, by Jay Tuttle, M. D.; Germ Theory of Disease, by Charles E. Banks, M. D.; Present Condition of Insanity Throughout the World, by S. E. Josephi, M. D.; Retarded Dentition, by Mrs. B. A. Owens, M. D.; Tuberculosis, by F. A. Bailey, M. D.; Laceration of the Cervix Uteri, by E. P. Fraser, M. D.

THE OLD AND THE NEW.—Our brethren in New York seem to be having a hard time of it with their new code. A meeting of the Academy of Medicine was held April 19th, which was quite largely attended, being, as it is charged, "packed" with the friends of the old and enemies of the new. After a couple of papers had been read and the usual programme had been followed, Dr. Austin Flint, Jr., rose and proceeded to read certain resolutions deprecating the admission of any Fellow who could not support the old code. These resolutions had been prepared secretly by one faction, to be rushed through when but a minority of the other were present. It seems to have always been the unwritten understanding that no questions of policy like this were to ever be discussed in the Academy. Its doings were to be either purely scientific or purely social. The county medical society was to be the arena where political questions were to be discussed. It was a genuine surprise, then, that these gentlemen should, under any circumstances, bring the matter up in the Academy, but most of all that no public notice was given to that effect. Only the friends of the measure knew as they went to the meeting that anything unusual was to occur. It was the desire to muzzle the liberals and to check all opposition. Those gentlemen who asked for opportunity to fairly discuss the matter on its merits were choked off at once, and with hisses and jeers. And so the resolutions were with indecent haste and by disreputable means adopted. The methods of these gentlemen who thus "got in their votes" were, to say the least, *peculiar*. We fear that if the Irish ever take Ireland it will be by adopting a similar policy, which we accordingly commend for that purpose. The profession and journals of the East are too fond of allowing themselves to misrepresent the doings of their Western colleagues as *crude*, and our Western educational advantages as inferior, and rather insinuate that out West we lack *tone*. After this riot in the metropolis, we feel certain that it can no longer be the high privilege of any member of the Academy, at least, to point the derisive finger westward. We might possibly institute comparisons between it and the Chicago Common Council, or a ward primary in the "bloody Fifth Ward," comparisons not particularly favorable to either side; but the most turbulent medical meeting ever held in the West would seem like a Sunday-school when compared with this session of the Academy. Imagine Dr. Agnew asking: "Then the object is to throttle this Academy?" and Dr. Flint, Jr., replying, "Undoubtedly it is!" Moreover, an amount of ill-feeling and distrust has been engendered by this action which will never subside during the present generation, and now it is being carried into the colleges and hospitals. For instance, Professor Howe, of Bellevue College, rather than recede from his position in favor of the new code when asked to do so, has just tendered his resignation. Rumors of other resignations fill the medical atmosphere; and so it goes, and the end is not yet.—*Weekly Med. Review*.

AMENDMENTS TO THE BY-LAWS OF THE COUNTY SOCIETY.—At a meeting of the Medical Society of the County of New York, held Monday evening, May 28th, Dr. Henry G. Piffard moved the following amendments to the by-laws:

1. No member of this society shall assume any sectarian designation indicating that his practice is based on any special doctrine, dogma, or specified method of treatment.

2. The members of this society shall be governed by the code of ethics adopted by the Medical Society of the State of New York February 6, 1882.

3. No person shall be eligible for membership in this society who is a member of a county society not entitled to representation in the Medical Society of the State of New York.

According to the rules, the first of these proposed amendments

has to lie over to the annual meeting. The second and third, being necessary to bring the by-laws of the county society into accord with those of the State society, were susceptible of immediate action, and were carried unanimously.

ARMY INTELLIGENCE.—*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from May 19, 1883, to May 26, 1883.*—**CAMPBELL, JOHN**, Lieutenant Colonel and Surgeon, Medical Director Department of the South. Granted leave of absence for one month, on surgeon's certificate of disability. Par. 3, S. O. 50, Department of the South, May 21, 1883. — **BURTON, HENRY G.**, Captain and Assistant Surgeon. Now awaiting orders at St. Paul, Minn., assigned to temporary duty at Fort A. Lincoln, D. T. Par. 1, S. O. 83, Department of Dakota, May 15, 1883. — **PORTER, J. Y.**, Captain and Assistant Surgeon. Assigned to duty at Fort Davis, Texas. S. O. 49, Department of Texas, May 14, 1883. — **SPENCER, WILLIAM G.**, Captain and Assistant Surgeon. Assigned to duty at Fort Hamilton, N. Y. H. Par. 2, S. O. 83, Department of the East, May 14, 1883. — **GORGAS, W. C.**, First Lieutenant and Assistant Surgeon. Granted leave of absence for one month. Par. 5, S. O. 51, Department of Texas, May 17, 1883. — **HOPKINS, WILLIAM E.**, First Lieutenant and Assistant Surgeon. Assigned to temporary duty at Whipple Barracks, A. T. Par. 2, S. O. 44, Department of Arizona, May 14, 1883. — **MACATELEY, CARTER N. B.**, First Lieutenant and Assistant Surgeon. Assigned to duty at Fort Bennett, D. T. Par. 2, S. O. 83, Department of Dakota, May 15, 1883. — **MC CREERY, GEORGE**, First Lieutenant and Assistant Surgeon. To report for duty to the commanding officer of troops in the field near San Bernardino Springs, A. T. Par. 1, S. O. 44, Department of Arizona, May 14, 1883. — **RAYMOND, H. I.**, First Lieutenant and Assistant Surgeon. Relieved from duty with troops in the field near San Bernardino Springs, A. T., and ordered to return to his proper station, Fort Apache, A. T. Par. 1, S. O. 44, Department of Arizona, May 14, 1883. — **WILSON, GEORGE F.**, First Lieutenant and Assistant Surgeon. Upon being relieved as Post Surgeon at Fort Townsend, W. T., assigned to duty at Headquarters Department of the Columbia. Par. 2, S. O. 64, Department of the Columbia, May 10, 1883. — **WILSON, GEORGE F.**, First Lieutenant and Assistant Surgeon. To report to First Lieutenant Frederick Schwatka, Third Cavalry, for duty in connection with explorations in the Department of the Columbia. Par. 3, S. O. 64, Department of the Columbia, May 10, 1883.

SOCIETY MEETINGS FOR THE COMING WEEK.—*Monday, June 4th:* Medico-Chirurgical Society of German Physicians; Morrisania Medical Society (private); Utica Medical Library Association. *Tuesday, June 5th:* American Medical Association (Cleveland—first day); Medical Society of the State of Ohio (Cleveland—first day); Medical Society of the County of Columbia, N. Y. (Hudson); Medical Society of the County of Franklin, N. Y.; Medical Society of the County of Herkimer, N. Y. (Herkimer—annual); Medical Society of the County of Niagara, N. Y. (Lockport—annual); Medical Society of the County of Orange, N. Y. (Goshen—annual); Medical Society of the County of Saratoga, N. Y. (Ballston Spa—annual); Medical Society of the County of Schoharie, N. Y. (Schoharie Court-House—annual); Medical Society of the County of Ulster, N. Y. (Kingston—annual); Medical Society of the County of Yates, N. Y. (annual); Medical Society of the County of Hudson, N. J.; Medical Society of the County of Warren, N. J.; New York Neurological Society; New York Obstetrical Society (private); Elmira Academy of Medicine; Buffalo Medical Association. *Wednesday, June 6th:* American Medical Association (second day); Medical Society of the State of Ohio (second day); Medical Society of the County of Cattaraugus, N. Y. (Ellicottville—annual); Medical Society of the County of Richmond, N. Y. (Stapleton); Medical Society of the County of Tompkins, N. Y. (Ithaca—annual); Ontario Medical Association (Ontario, Canada). *Thursday, June 7th:* American Medical Association (third day); Medical Society of the State of Ohio (third day); Society of Physicians of the Village of Canandaigua, N. Y. *Friday, June 8th:* American Medical Association (fourth day); Medical Society of the Town of Saugerties, N. Y. *Saturday, June 9th:* New York Medical and Surgical Society (private).

Lectures and Addresses.

LECTURES ON HUMAN AUTOMATISM.

DELIVERED AT THE LOWELL INSTITUTE, BOSTON.

By WILLIAM B. CARPENTER, M.D., LL.D., F.R.S., Etc.

LECTURE V.

Automatism of the Motive Powers.—Cravings and Desires immediately connected with Animal Appetites. Higher Forms of Emotion and Passion connected with Ideational States. Influence of the Will in controlling and directing these by Determinate Fixation of Attention.

THERE is no part of our perceptual experience which can be studied with more interest and value than that which relates to our appreciation of direction, of distance, and especially of solid form; for we have here the means of clearly ascertaining that this is an acquired automatism, and is not, as in the lower animals, directly and immediately intuitive. Every one knows that a chick just hatched, as soon as it can stand upon its legs and run about, will peck at an insect before it, and peck successfully. Most of you must have had the opportunity of observing, on the other hand, that an infant lying in its cradle, when a watch or some other bright object is held up before it, feels about for some time before it grasps it, thus showing that, though it can recognize direction, it does not appreciate distance. But it is by the observation of children, and sometimes of adults, who have obtained sight after having either been born blind or having lost it in early infancy, that we have our best means of studying the manner in which the visual sensations received from any object have to be co-ordinated with those of touch—using this last term, in its most extended sense, as meaning not only the sense of contact with the fingers, but that given by the movement of the hand toward and over the object in “feeling” it. Those of you who have not attended to the subject would scarcely be able to conceive the necessity of this co-ordination, so completely and harmoniously do the two senses work together in our ordinary experience. It was Locke, I think, who put the question whether, if a cube, a sphere, and a pyramid, with the solid forms of which a person born blind had become familiar through his touch, were placed before his eyes when he first acquired distinct vision, he would be at once able to recognize and distinguish their visual images, so as to name each aright. The question was a proof of the sagacity of the questioner; but it could not then be answered with any certainty. Subsequent experience, however, has given us the power of affirming that a person so circumstanced could *not* recognize these or any other forms, whatever might have been his previous tactile familiarity with them, by his sight alone. For several cases have now been carefully observed in which it has become perfectly clear that the visual recognition of an object previously known through the tactile sense can only take place after an experiential combination of the two different orders of sensational experiences into one perception. In the first of these

cases, recorded by the celebrated surgeon Cheselden, within Locke's own time, a young gentleman, intelligent and able to give an account of his own perceptions, had been operated on for congenital cataract, and soon obtained enough sight to be able to describe the appearances of what he saw. As only one eye was operated on, it may be objected that he could not have enjoyed that visual perception of *solidity* which we derive (as I shall presently show you) from the conjoint use of two eyes; but the want of the second eye could not have interfered in the least with his perception of *flat* forms. And it soon became clear that he could not recognize the visual images of objects with which he had been all his life familiar through his touch. Among other things, it was mentioned that he was continually mistaking between a cat and a dog which he had been accustomed to caress; and that, having become rather ashamed of his mistake, he one day took up the cat which he had miscalled, held her in his hands for some time, felt her well over, looking at her the while very intently, and then, putting her down, said: “So, puss, I shall know you another time.” I had myself in early life the opportunity of seeing a case of this kind—that of a very intelligent lad between two and three years old, the child of a farmer near Bristol, England. This child had been accustomed to run about his father's farm-yard, was perfectly familiar with the whole place by feeling, knew every animal in it, and was known by every one; he was a very fine, fearless little fellow, and was so strong and sturdy that it was with great difficulty that he was held down while the operation for cataract was performed. It was very soon apparent, from the clearness of the pupils of his eyes, that he must be receiving impressions of light and of the forms of objects; and this soon showed itself in his accounts of what he saw, but still more in his actions. It was a great delight to him to run round a dark, polished mahogany table, on which some bits of white paper were laid, while blowing these about its surface; the unexpectedness of their movement (which was altogether outside his previous experience), the sense of his own power to produce it, and, I should suppose, the enjoyment he had in the exercise of a sense entirely new to him, making him shout with glee at the effect of each puff. Thus it was clear that he *saw* the papers, and was learning to direct his movements in accordance with his visual sensations. Now, he had been brought from his country home into lodgings in Bristol for the operation to be performed; and those among whom he there was were able to watch his gradual acquirement of the co-ordinating power, in the manner of his going about the house in which he was. He would feel with his hands, and at the same time look with his eyes; but, having acquainted himself well with the place before he obtained sight, he at first preferred the guidance of his hands to that of his eyes, and seemed rather puzzled than helped by his visual experiences. In the course of two or three weeks, however, he found his way about the house perfectly well by his sight alone. When, however, he returned home with good sight, the puzzled condition reappeared. He had such a tactile familiarity with the house, farm-yard, and animals, that it was an obvious perplexity to

him to see them; for he used to shut his eyes in going about, and even continued to do this for some time. He had gradually to learn by experience to combine the visual picture with the perception which he had previously acquired through his touch. But his parents reported that, while he was still obviously puzzled by his sight at his own home, he always used his eyes when he went to a new place—not having got any previous impressions of it to work, as it were, into his perceptive fabric, but gathering his knowledge of it through the two senses at the same time, so as to be constantly weaving together, as it were, the two sets of suggestions into a single complete perception.

There has been a subsequent case of the same kind, operated on by a friend of mine, the late Mr. Critchett, in London: that of a young woman who had been accustomed to work with her needle. She had a little sight previously to the operation, though not enough to enable her to distinguish objects; and though the sight she acquired by it was not very good, it sufficed to enable her to recognize and describe the general forms of objects. Now, it will perhaps rather surprise you to be told that she had not the least idea of what a pair of scissors was when it was held up before her, notwithstanding that she had become perfectly familiar with the implement by having constantly handled it; she was herself much astonished, and accused herself of stupidity; and then, like Cheselden's patient, she took the scissors into her hands and looked at them steadfastly, so as to bring the two sets of sensations into co-ordination.

These facts will show you that we have to go through an education in the combination of our visual and tactile sensations into perceptions of external objects analogous to that which we have to go through in the co-ordination of our muscular movements in the balancing of the body. And, in the one case as in the other, when we have gone through that education, we have no further difficulty in the matter, though we are occasionally liable to fall into error (as I showed you at the close of the last lecture) by trusting to the intimations of our visual sense alone. And it is further clear that it is by this combination that we not only harmonize our visual and tactile perceptions of *figure*, but are led by it to the conception of *solid form*. No retinal picture can of itself call up in the mind any other perception than that of a surface of *two* dimensions. We first learn the existence of *three*, while handling solid objects in our infancy, and turning them in various directions, so that they present different visual aspects. And when we have once learned the relation between solid form as represented in a picture, and solid form as apprehended through the touch, the former, in virtue of that acquired automatism, suggests the latter, the image of any solid that is formed on the retina of one eye only being perceptively interpreted—in virtue of our acquired automatism—as that of an object of three dimensions. But monocular vision, as I shall presently point out to you, may suggest an erroneous interpretation, our perceptive judgment being liable to modification by preconception. And I have now to show you how constantly we depend upon *binocular* vision alike for our perceptions of solid form and for our recognition of the relative distances of near objects.

The late Sir Charles Wheatstone, as you are doubtless aware, was the inventor of the instrument known as the stereoscope. The present form of it, which is to be found, I suppose, in most of your houses, was not its original form. The first stereoscope devised by Wheatstone consisted of a pair of mirrors so placed before the eyes as to bring to them, by reflection, pictures placed one on the right side and the other on the left. Its effect, however, was exactly the same as that of the stereoscope with which you are familiar. Now, when I hold up a solid object—a closed book, for instance—within distinct visual range of both my eyes, I receive two dissimilar retinal images of it, as I at once come to perceive when I close either eye and compare the shape which I then see with that which I see through the second eye when the first is closed. Now, the older writers on vision were quite aware of this difference between the two retinal perspectives of near objects, but supposed that the mind merely unified them. It occurred to Wheatstone, however, that this very dissimilarity might be the basis of that perception of solid form which we *unmistakably* derive from the conjoint use of both eyes; and he devised the original stereoscope as a means of putting this idea to the test. "If," he reasoned, "our perception of solid form is derived from the co-ordination of the two dissimilar retinal perspectives of an actual solid object, it ought to be produced with equal vividness and certainty by throwing upon the two retinæ two dissimilar perspective representations of the object, as seen by the right and the left eyes, respectively." Choosing simple geometrical solids as the forms most simply and truthfully represented in linear perspective, he drew two projections of a cube, for example, placed at the distance of a foot in front of the nose, as seen with the right and left eyes respectively, and found that when, by means of his mirror-stereoscope, each perspective was thrown on the corresponding retina, the mental image was that of the projecting solid, not that of either of the dissimilar perspectives.

I shall illustrate this to you by a pair of projections of a different form—a hollow truncated pyramid, which I take as serving also for the illustration of the "conversion of relief" which is produced by the reversal of the two perspectives. It is obvious that if such a pyramid be held up in front of the nose, with its small truncated end nearest the eyes, the observer will see more of its right slope with his right eye, and more of its left slope with his left eye, as shown in the two upper perspectives A and A', so that the two small squares representing the truncated end in each projection will be perspectively approximated to each other. If, on the other hand, the base of the hollow pyramid were turned toward you, so that you would look into its interior, you would see more of its left slope with your right eye (as at B), and more of its right slope with your left eye (as at B'), and the two truncated ends would be perspectively separated from each other, as in the lower pair of projections.

Now, if the upper pair of pictures be projected by the stereoscope on the right and the left retina, respectively, the perception of a *projecting* pyramid is vividly called up; while if the lower pair be similarly projected, a *receding*

pyramid is mentally perceived with equal vividness. Many persons find it possible thus to combine stereoscopic pictures, without the use of the stereoscope, by a kind of squant-

FIG. 1.—PERSPECTIVE PROJECTIONS.

A, A', of a *solid*, and B, B', of a *hollow* truncated pyramid, as seen with the right and the left eyes, respectively.

ing, which duplicates the pictures. If the left-hand perspective be thus projected upon the right, and the attention be steadily fixed upon it, a true stereoscopic representation of the solid is obtained. Having accustomed myself to do this with small pictures within a short distance from my eyes, I have found myself able to do it, when seated in various parts of this hall, with the large figures now before you; and I think it likely, therefore, that many of you may be able to obtain the same effect. Now, you will see that the two perspectives of the upper pair are precisely similar to those of the lower pair, only their relative positions being different, so that, if we draw the two figures on separate cards, we get the perception of either the projecting or the receding pyramid by simply changing the place of either of them to the opposite side of the other.

This "conversion of relief" is a very singular and interesting phenomenon, and is clearly the result of that education of our perceptive faculty of which I have spoken. Our minds have become so familiar with the conception of the solid forms of objects, derived from the dissimilarity of the pictures thrown by them upon our two retinæ, that a like dissimilarity between two properly projected plane figures, thrown on the right and left eyes, respectively, vividly presents to our minds the object which would produce it. Here, then, is an automatic combination which we are constantly making without the least consciousness of it; and when two stereoscopic figures give us the visual perception of a solid object that is not really present, it is because the simultaneous transmission of the physical impressions produced by these two pictures upon our right and left retina, respectively, produces the same effect upon our sensorium as if these pictures had been formed by our eyes directly from the actual solid object they represent.

I might follow out this subject into considerable detail; in fact, I might very easily give a whole lecture upon it.

It is one that has been a subject of great interest to myself, through my having been in intimate relation with Sir Charles Wheatstone, whose cause I had occasion more than once to take up as the real inventor of the stereoscope, and the real discoverer of the principle that, in the ordinary vision of near objects, it is the mental combination of the two dissimilar perspectives that fall upon our right and left retina which produces the effect of projection, the stereoscope, which enables us to obtain the same effect from two suitable pictures, proving this to be the fact.

Sir Charles Wheatstone made a great number of other most interesting researches upon binocular vision, to one of which I must refer, because it will show you by experimental proof how intimately our perception of the sizes and distances of near objects is connected with the conjoint use of the two eyes. You may say that persons who only see with one eye form the same perceptive judgments on these points as those who use two; and this is to a certain extent true. All those visual perceptions which are originally derived from the co-ordination of the senses of sight and touch can be acquired by a one-eyed as well as by a two-eyed child. But we may easily find out, by experimenting upon ourselves, that, when we use only one eye, we do not possess the same power of *unmistakably* measuring the relative distances of near objects,* or of distinguishing between a solid form and a picture which well represents it, that we have when we use both eyes conjointly. And the perceptive judgments formed by one-eyed persons on these points are open to the same fallacies as are the judgments which we ourselves form in regard to remote objects, our perception of which is in no way advantaged by the conjoint use of both eyes.

One of Sir Charles Wheatstone's ingeniously contrived experiments was directed to the solution of this question: Why is it that, if I hold up a book or any other object at arm's length in front of my eyes, and then bring it to (say) half its previous distance, its size does not seem augmented, although the linear dimensions of its retinal picture must have been doubled so as to equal those of an object of twice its dimensions held at the original distance? It occurred to him that the explanation might lie in an allowance instinctively made for the approximation of the object, which serves to correct the estimate based on the size of the retinal picture, this automatic correction depending on the increased convergence of the axes of our eyes, as the object to which they are directed is brought nearer to them. In order to bring this supposition to the test of experiment, Wheatstone so modified his original reflecting stereoscope that, while the distances of the two pictures from the eyes remain virtually the same (so that the size of their retinal images undergoes no change), the angle of convergence of the optic axes can be made to increase or diminish. This he effected by pivoting the two side-arms that carry the pictures so as to rotate round a central axis fixed between the mirrors; whereby, the pictures being

* Thus, if a large ring be suspended by a string a yard from the eye, and the attempt be made with one eye closed to pass the crooked handle of a walking-stick through it sideways, it will rarely succeed until after several repetitions.

moved round in the circumference of the circle at a constant distance from the center, the angles at which the rays proceeding from them are reflected by the mirrors to the two eyes, respectively, undergo enlargement or reduction, requiring for the reception of those rays and the formation of retinal images of the pictures an increased or diminished convergence of the optic axes. The result is, that the pictures so made to rotate appear to undergo a most remarkable change of dimension, according as the convergence of the optic axes is increased or diminished, although the size of their retinal images remains unchanged. When the arms carrying the pictures are so moved that the angle of convergence is *increased*, the apparent size of the pictures is notably *reduced*, this increase of convergence affecting our perceptive mechanism in the same way that an actual approximation of the object would do; and as the customary enlargement of the retinal picture conformable thereto does not take place, the resultant effect upon the

FIG. 2.—DIAGRAMMATIC REPRESENTATION OF WHEATSTONE'S IMPROVED REFLECTING STEREOSCOPE.

The two mirrors, M and M', placed at right angles to each other, receive the rays (marked by the dotted lines) proceeding from the pictures, P P' (carried by the arms C P and C P'), and reflect them to the two eyes in the positions E and E'. When, as in the upper figure, the two arms lie in the same straight line, the rays reflected to the eyes come to them in parallel lines; but when, as in the lower figure, the two arms have been made to rotate round the center, C, so that the pictures come into the positions P and P', the rays reflected to the eyes come to them in lines diverging from a virtual focus, F, toward which the optic axes converge to receive them.

mind is in the contrary sense. And, conversely, when the arms are made to rotate in the other direction, so that the axes of the eyes become *less* convergent, and then parallel, the apparent size of the pictures undergoes a most remarkable *increase*, the effect upon our perceptive mechanism being the same as that which the removal of the pictures to a much greater distance would produce, while the visual picture corresponds to that of a much larger object at the increased distance thus suggested.

Here, then, we have an example, previously quite unsuspected, of the unconscious working out of a simple perceptive resultant by the composition of two factors; and I know no more singular and apposite example of the automatism of our nature than that which is furnished by Sir

Charles Wheatstone's beautiful analysis of this process. You can all make for yourselves a simple experiment, which will give you a corresponding result. If, when you are watching the arrival of a railway-train at a station, you stand sufficiently far back on the platform to take in its *side* view, you will not see any apparent enlargement in its size as it approaches you, because the progressive increase in the dimensions of its retinal image is counterbalanced by the visual perception you simultaneously form of its correspondingly diminished distance. But if you place yourself on, or close to, the line of rail beyond the point where the train is to stop, so as to see it coming in *end on*, it will seem to swell out rapidly the nearer it approaches; for, although you know as a matter of fact that it is coming nearer to you, its approximation does not impress itself on your perceptive mechanism, and the suggestion given by the increased size of the retinal image is, therefore, uncompensated by the suggestion of diminished distance, thus giving the effect of apparent enlargement of the object.

I may add a personal experience of my own, which may be of interest to you. My scientific work in the Mediterranean having given me an opportunity, some years ago, of visiting the Pyramids, I found, while driving along the road which leads to them, and having them in full view before me, that, as soon as I was able to distinguish the courses of stone of which they are built, their apparent magnitude underwent a notable diminution. For these courses looked so like brick-work that, although I intellectually knew them to consist of stones from three to four feet high, my perceptive mechanism constructed the whole mass (as it were) on the brick-work scale; and it was not until I stood at the base of the Great Pyramid, and measured the courses of its stones against my own height, that the gigantic dimensions of these wonderful monuments came back to me.

I can scarcely doubt that this automatic formation of perceptive judgments is based on *acquired* experiences; and that its mechanism is laid down during that early stage of our lives in which the co-ordination of the various impressions received through the organs of sense is the first work of the dawning intelligence, the basis being thus laid of all that the individual subsequently comes to know of the world in the midst of which he is placed. Any one who attentively watches the eyes and the actions of an infant in its cradle must see that it is not only educating itself to the appreciation of solid form, but is learning to connect the visual perception of the distances and directions of objects brought near to its eyes with the muscular and tactile measurements it makes in stretching out its hands to grasp them. There is every reason to regard this visual measurement as dependent in the first instance on the *sense* of the convergence of the optic axes; and this notwithstanding that we come by habit to make it without any *conscious* recognition of that convergence; just as, in ordinary walking, we maintain the balance of our bodies without being made aware of that constantly repeated disturbance of it which alarms the young child in his first attempts at biped locomotion.

"The eye," says Carlyle, "sees what it brings the power to see." But it is the eye of the mind, rather than that of

the body, to which this observation most truly applies; and what we call the education of the eye is really the improvement of our power of perceptive recognition of the higher meaning of the sensory impressions which we receive through its instrumentality.

(To be continued.)

Original Communications.

ON SOME COMPOUND ARTICULAR FRACTURES.*

By LEWIS A. STIMSON, M. D.,

PROFESSOR OF PHYSIOLOGY IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

THE surgery of the joints has already received in the discussions of this society an attention to which the importance and variety of the lesions with which it deals, the permanent disabilities which these lesions so frequently cause, and the difficulties and embarrassments encountered in their treatment, fully entitle it. Among the more important traumatic lesions, compound fractures hold a prominent place. Equally with other injuries, they have shared in the benefits conferred by the recent great improvements in the treatment of wounds, and, so far as the severer forms are concerned, the rules of treatment have been drawn with sufficient distinctness. You will all, doubtless, remember cases that have been presented here in which formal primary excision of a joint that has been extensively mutilated in all its parts has not only saved the limb, but has also given the patient a new and useful joint. My wish is to ask your attention this evening, not to these extensive injuries in which the question lies between excision and amputation, but to those lesser ones in which, the injury to the bone and soft parts being comparatively slight, the main feature is the implication of the joint, and the therapeutical problem is how best to avoid dangerous suppuration within it—cases in which the surgeon asks himself whether he is justified in striving for preservation of form and function, in seeking to convert the fracture into a simple one, in depending upon drainage and antiseptics to prevent suppuration, or whether he should not rather seek, in partial or complete excision, an inferior result, but one obtained with less risk to the patient. The cases I have now to relate are those of this class which have come under my care during the past year; they are three in number, one each of the elbow, knee, and ankle.

CASE I.—W. J. K., twenty-eight years old, fell to the ground, April 4, 1882, from the seat of a truck which he was driving, struck upon the palm of his right hand and injured his elbow. He went at once to a small hospital, where, he says, the limb was handled for some time, causing him much pain, and he was then advised by the examiners to seek relief elsewhere. He came to the Presbyterian Hospital, where I saw him five hours after the accident, and recognized a dislocation backward at the elbow of both

bones of the forearm. Ether was administered, at his request, and the dislocation reduced easily. The skin was unbroken.

On further exploration, I found a movable, hard body, about half an inch long, lying under the skin on the outer side of the joint between the head of the radius and the olecranon, which—as the outlines of the olecranon, external condyle, and the accessible portion of the head of the radius were normal—I judged to be the inner portion of the head of the radius broken off when the bone was forced backward past the condyle. Believing that if left in place, or even if restored to its proper place, if that were possible, it would interfere very seriously with the subsequent mobility of the joint, I removed it at once by cutting straight down upon it. The joint was then washed out with a watery solution of carbolic acid, 1 to 40, a short drainage-tube inserted, the wound closed about it with two sutures, and a gauze dressing applied.

The fragment, which I now show, is a portion of the head of the radius, triangular in shape, comprising about one third of the articular surface. It is 17 mm. long, 12 mm. wide, and 8 mm. thick, the latter measurement being in the direction of the longitudinal axis of the bone.

The patient's temperature, which reached 102° the first evening, sank steadily to 98.5° on the morning of the eighth day. The dressing was not changed until the third day, when the tube was removed, and again on the eighth day, when the wound was found almost dry, and when I moved the joint through an arc of about 70°, rotated the wrist without causing pain, and reapplied the dressing. The patient left his bed shortly afterward, without permission, and walked about for two hours. In the evening the joint became painful, the temperature rose to 100.75°, and the next morning to 103°, when I removed the dressing and found no discharge, but the outer side of the joint was tender on pressure, red, and swollen. Reapplied dressing; posterior splint; ice-bag. Two days later (the eleventh day), the wound discharged about two drachms of pus on pressure, and during the following week discharged freely on pressure over the outer side of the elbow. On the nineteenth day I made a counter-opening on the outer side of the arm about three inches above the wound, and on the twenty-fourth day opened a large subcutaneous abscess on the inner side of the elbow, which communicated with the other, apparently by a track passing around posteriorly above the elbow. The flow of pus then diminished rapidly, and the opening closed within a month. As the joint was only slightly movable, I forced it, under ether, on June 8th, getting motion through a range of about 60°. When I last saw the patient, a week or two later, the greater part of this gain had been lost; the joint was free from pain, and the patient resumed work as a driver, promising to report from time to time. I have heard nothing from him since.

[May 23, 1883.—I met this man to-day. Flexion and extension at the elbow are almost complete, but rotation of the forearm is entirely lost. The arm is strong and serviceable.]

CASE II.—Edward C., twenty-two years old, was admitted to the Presbyterian Hospital, February 4, 1883, with

* Read before the New York Surgical Society, May 8, 1883.

a compound fracture of the left patella, caused the same day by a fall from a pillar of the elevated railway which he was attempting to climb while intoxicated. The bone was broken transversely a little below its center, without comminution, and the fracture communicated largely with a clean-cut, transverse wound, one inch and a fourth long, lying directly in front of it; the edges of the wound and the surrounding parts showed no signs of having been bruised. The trousers showed a corresponding transverse cut at the knee. There was also a fracture of the left inferior maxilla, and a long vertical wound of the left cheek. The knee was dressed with carbolized gauze, and the limb placed on a single-inclined plane.

The next day, when I first saw the case, I found the wound and the interval between the fragments occupied by a clot, removed it, enlarged the wound for half an inch on the inner side, washed out the joint thoroughly with a 1 to 20 carbolic solution, passed a drainage-tube into the joint on each side through an opening made at about the center of the lateral aspect, brought the fragments together with a silver-wire suture, the loop of which included all the soft parts except the skin in front, but not the articular cartilage, brought the ends out through the incision, closed the wound with sutures, and applied a gauze dressing covered with cotton bound on firmly. Posterior straight splint.

The dressing was changed the next day because of pain, and not again until three days later, when pus was found to have formed under the skin on the outer side, rendering necessary a counter-opening three inches above the one made for the drainage-tube on that side. The patient's general condition was satisfactory; temperature $99^{\circ}25'$. Three days later (February 12th) the drainage-tubes were removed, and a fresh one inserted on the inner side, under the skin alone, to drain a small cavity which had formed around and above the tube. During the following week the dressing was changed every second or third day, and the patient seemed to be doing well, but his temperature rose every afternoon to 101° , and on the 21st of February he complained of pain on pressure in the lower part of the thigh, which was swollen and rather tense; there was, apparently, no liquid in the joint; the openings yielded only a small amount of thick, creamy pus on pressure. February 24th I opened a large collection of pus which lay on the outer side of the lower portion of the thigh under the vastus externus, and which communicated imperfectly with the opening made by the drainage-tube on that side, and also with the outer angle of the wound. The incision made on this occasion was about six inches above the condyle. Drainage-tube. After this the temperature sank to the normal level, the thigh shrunk to nearly its natural size, and the amount of pus diminished steadily.

March 12th it is noted that the case had progressed satisfactorily during the preceding fortnight; the abscess on the outer side of the thigh had shrunk to the track of the tube, the last portion of which was removed that day; the pouch on the inner side had a capacity of about one ounce; the transverse wound in front of the patella was flat and partly cicatrized. The wire uniting the fragments was cut and re-

moved on that day. The patella was movable laterally, and the knee could be flexed slightly without pain.

March 30th, the dressing, which had been in place eleven days, was changed; all the openings except the two first made for the drainage-tubes were closed, and the anterior wound had nearly cicatrized. The fragments of the patella were united apparently by a fibrous band about one fourth of an inch long, and were movable upon each other.

The patient was discharged from the hospital April 2d, with instructions to wear a posterior splint and report in a fortnight. April 14th everything was found healed except the tube opening on the outer side. Patient walks without a crutch, and can flex the knee ten degrees without pain. Independent mobility of the fragments can not be recognized. On the 30th of April I removed a small fragment of the patella that was found under the skin just above the opening of the drainage-tube on the outer side, and which had kept up suppuration at that point. The patella was now freely movable laterally, and the mobility of the joint was increasing.

CASE III.—Thomas S., forty-seven years old, was admitted to the Presbyterian Hospital, February 17, 1883, with a compound fracture at the left ankle, caused by a fall while walking in the street half an hour before admission. Intoxicated.

The left fibula was broken at a point about three inches above the tip of its malleolus; the internal malleolus was broken off at its base, and this fracture communicated with a transverse wound of the skin directly over it, through which blood was flowing quite freely. A small piece of bone which lay in the wound was removed. The surface of the wound was washed with the carbolic solution, but the wound was not injected. A gauze dressing was applied, with side splints outside. The next day the dressing, which was saturated with blood, was changed. The patient was very tremulous, with slight hallucinations. On the third day the dressings were again changed, the position of the foot corrected, a posterior and an external lateral splint of plaster of Paris applied next the skin, and a new dressing placed over all. This dressing remained in place until February 26th, the tenth day, when the discharge came through. During the first seven days the temperature did not rise above 99° . On the eighth day it rose to $99^{\circ}5'$, and on the tenth to 100° . The alcoholic symptoms had disappeared by the end of the first week.

March 5th the wound was found to be reduced to a small, flat sore, and a small cotton dressing was substituted for the gauze. March 18th the wound was found entirely healed; a continuous plaster splint was applied from the toes to the knee, and the patient was discharged March 24th at his request. May 7th I learned that the joint was freely movable and painless; the patient had returned to work, and was troubled only by the swelling of the limb during the day.

While in the last case the course was entirely free from complications, and the result as satisfactory as after any simple fracture, and although in the other two the patients' lives were never in danger, and there was never even any anxiety concerning them, except such as is inseparable from

a knowledge of the possibilities in such cases, yet in each recovery was delayed, the result marred, and the chance of the occurrence of dangerous complications notably increased by profuse and prolonged suppuration, and in each the course differed widely from the uneventful, uninterrupted, rapid progress to recovery seen in the third case, which is the ideal of treatment, and which many believe a rigorous use of the complete antiseptic method will insure.

It would be manifestly improper to assume that this difference in result was due solely to differences in the treatment of these cases; such a generalization from so limited a number of cases would be unwarranted; but a discussion of these differences may not be without value, and may bring out such details of experience and expressions of opinion by you as will enable us to formulate more closely rules of treatment to be applied in similar cases. The details of treatment and the differences were as follows:

In no case was the spray used, neither in the first nor in any subsequent dressing. At the first dressing the wound was injected with the carbolic solution in the first two cases; in the third case only the surface of the limb and wound was washed with the same solution. At no subsequent dressing was the wound in either case injected; at the most, a sponge saturated with the solution was squeezed over it. The dressing was the common carbolized gauze, applied dry in a single broad sheet of several thicknesses, or in several narrow strips, overlapping and crossing each other somewhat like those of a Scultetus bandage, for the sake of an easier and more accurate fit, bound on singly with a roller bandage, and sometimes overlaid with a thick layer of cotton to equalize the pressure. The dressing was changed whenever the discharge came through, or whenever pain or a rise of temperature made inspection of the wound desirable. The drainage-tube in the first case was short, reaching, probably, down to the wound in the capsule, but not into the joint. It was removed on the third day. In the second case—fracture of the patella—a drainage-tube was passed into the joint on each side, and left in place for a week. In the third no tube was used.

In the second and third cases the joint was kept completely immobilized upon a splint for several weeks; in the first case it was immobilized for one week, and then, after the occurrence of suppuration, again until the cure was nearly complete.

There was no evidence of putrefaction of the discharge in either case; and, in the two that suppurated, the drainage was efficient, and the pus came, not from the joint, but from cavities that formed in the cellular tissue beneath the skin, and in one beneath the vastus externus. Why did these collections form? Why did suppuration occur at points so distant from the openings in the skin?

In the first case there appears to be a very definite, immediate determining cause—the passive motion communicated on the eighth day, together with the use of the arm immediately afterward in dressing and moving about. Up to this time the patient had been doing very well, the swelling had subsided, and the wound was little more than a superficial sore. The swelling that followed the receipt of the injury was not greater than that commonly observed

immediately after a dislocation of the elbow, and the passive motion was even much less than that which is frequently communicated in the treatment of the same injury. There must, therefore, have been a secondary contributing cause, and that second cause I am disposed to find in the adjoining partly healed track of the drainage-tube, the two acting upon the loose cellular tissue, modified in its nutrition, and irritated by the previous swelling.

In the patella case similar conditions existed; pus formed outside the joint, and escaped alongside the drainage-tubes. The later abscess, which formed under the vastus externus, and required a separate opening, was a simple abscess by proximity or by direct continuation, such as is frequently seen.

The almost uninterrupted series of successes recently obtained in various arthrotomies done for the relief of deformity, specially in genu valgum, which are among the most brilliant triumphs of antiseptic surgery, shows that a compound articular fracture, produced by the surgeon with the minimum of violence and of injury to the surrounding soft parts, can be safely received and promptly repaired. In such cases, as also in those which have here been narrated, the joint is opened and a drainage-tube is commonly used. The differences, therefore, to which I think we must look for an explanation of the difference in the result lie in the greater injury done in the latter to the soft parts, to the swelling, and to the occasional delay in beginning treatment—a delay for which thorough disinfection does not entirely compensate.

Again, if we compare the course of simple dislocation of the elbow with that of the first case, the principal difference is found in the addition in the latter of an incision, the presence of a drainage-tube for forty-eight hours, and the persistence for a few days of the unhealed track of that tube; and this difference was sufficient, with the aid of the slight irritation of motion, to provoke suppuration in the swollen tissues. The inference to be drawn is, I think, that the unbroken skin furnishes a protection for injured or irritated tissues for which antiseptic dressings and treatment are an uncertain substitute, and that we should be cautious in inferring that we can safely deal with such tissues in accordance with experience obtained in operations upon those that are uninjured and unirritated. There is reason to think that, if this elbow had been kept at rest for a few days longer, suppuration would not have taken place; but still, would it not have been better to postpone the operation itself, to have removed the displaced fragment of the head of the radius only after the subsidence of the irritation caused by the dislocation?

Of these three cases, the one that did best was the one that was least interfered with (it was also the one in which the injury was least, but the difference in this respect was not great enough, I think, to account for the difference in the results), and I find in this fact, and in the fundamental success obtained in all, ground for the belief that confidence in modern methods of treating wounds should incline the surgeon rather toward absolute conservatism than toward operative interference; that in cleanliness, drainage, and rest, we have agents efficient in themselves to avert inflam-

mation of the joint, or, failing that, to keep the inflammation within such limits that the risks of an operation, if it should become necessary, are not materially increased; that the safeguards now possessed against the occurrence of formidable complications of wounds should give confidence to expect the comfortable healing of wounds accidentally inflicted, rather than stimulate to the voluntary creation of new ones; and that the broad rule of treatment in cases such as those under consideration should be to avoid excision, except when it is clearly indicated by the extent of the injury, the difficulty of establishing drainage, or by an economical reason arising from the function of the joint involved and the social condition of the patient that may make mobility, even if combined with some insecurity, preferable to ankylosis.

THE CLIMATIC TREATMENT OF PULMONARY CONSUMPTION; REPRESENTING THE OPINIONS OF THE PROFESSION IN REFERENCE TO CLIMATOLOGY AND CONSUMPTION.

By J. HILGARD TYNDALE, M. D.,

NEW YORK.

THE assemblage of morbid phenomena, known as pulmonary consumption, presents itself as the concurrence and co-operation of local inflammation and general infection. In a fully developed case of phthisis, inflammation and infection are associated in all possible degrees of intensity and chronicity.

For our purposes, this clinical division will serve to embrace all forms of consumption: 1. *Superficial processes of the respiratory tract*, a sluggish catarrhal condition, with only moderate changes in the underlying connective tissue; chronicity still limited, as regards duration, to a few months; general health impaired, and forming, not only the original immediate cause, but also the chief factor by which the present inflammatory condition is kept up.

2. *Chronic cavities*, with more or less peripheral infiltration, and infiltrations with bronchiectasis, both occurring either as slowly progressive from their incipency, or as remnants of past acute inflammations. In other words, gradual excavations and condensations, or the remains of acute processes, which have caused ulceration and shrinkage.

3. *The colliquative condition* of any form of phthisis.

Acute intermittent and remittent exacerbations form part of the history of most cases. Now, these conditions may attack the originally robust or the hereditarily vulnerable; the latter those with irritable skins and mucous membranes. As between the robust and the irritable there are, of course, numerous shades of resisting power.

In the climatic treatment of consumption we aim to put the patient under such climatic influences as will tend to counteract both infection and inflammation where they exist together, or either separately, where the recognition of this fact is possible.

The chief constituents of climate are:

1. Barometric pressure—differing at various elevations and with different degrees of humidity.

2. Temperature—mean degrees and equability.

3. Humidity—relative dryness.

What, now, is an atmosphere suitable to phthisis? The three prime requirements of such a climate are a certain elevation, more or less dryness, and reasonable equability of temperature, coupled with the uniform absence of extremes of temperature—excessive heat or cold. Out of the relations of these three constituents to each other we may formulate this great general rule: *Whichever constituent may be the most necessary to prescribe—dryness, elevation, or equability—neither must be permitted to be coupled with a mean temperature of extremes—heat or cold.*

What is wanted is an aseptic atmosphere at from sea-level to high altitude, in which various degrees of dryness and equability of temperature are found in the company of warmth or coolness.

Dryness is the proper antidotal element for infection.

Equability is the antidotal element for irritation and consequent inflammation.

We know that: 1. Equability precludes cold.

2. Dryness precludes heat and excessive moisture.

Upon this basis a climate should be selected in which either dryness or equability predominates. When thus we have judged *objectively* of the preponderance of local inflammation or general infection, we may judge *subjectively*, by consulting the patient with regard to his feelings and preferences for warm or cold weather generally. The degrees of temperature are to be chosen *in accordance with the sensations of the patient.*

The irritable, of ready vulnerability, are not able to bear a stimulus to increased functional activity, such as is found in a dry and rarefied atmosphere. What in average cases is a stimulation to increased digestion, assimilation, and sanguification, is to them an irritation; a frequent cause of acute exacerbations. This rule applies, therefore, to the acute exacerbations also, since they result from a sudden or persistent co-existence of cold and moisture, and need the opposite conditions—warmth and moderate dryness.

Patients in the colliquative stage should remain at home.

In order to ascertain the opinions of those of the profession who have given more or less attention to climatology, I addressed a circular letter to them. Eighty-six answers were received from all parts of the country. The best view of their opinions is had by reviewing the constituents of climate *seriatim*.

1. ELEVATION.

For convenience' sake, we recognize low, medium, and high altitudes. The "line of immunity" is rather arbitrarily fixed at six thousand feet in our latitudes. The fact is, that immunity is to be found at such elevations where, aside from dryness, there is the nearest possible approach to equability. A moment's reflection will then explain why the elevation for immunity increases toward the equator. It is because there is no difficulty in obtaining equability in the tropical zone, but it is in the bad company of moisture; and if, as between dryness and equability, the demand for dryness should be satisfied first, it will require additional (and under the equator considerable) elevation to meet this demand.

Coolness and dryness increase with elevation. Pressure of the air-column is diminished. With a diluted air and little moisture to pass through, the sun's rays heat the earth rapidly; but for the same reason, which prevents the formation of a moisture diaphragm, the heat is radiated skyward at night. Hence, equability is not found with elevation and dryness.

The question was asked as to the value of elevation as a curative agent, and if so because we expect to find fresh air in abundance only, or because the atmosphere is relatively free from disease germs—an aseptic atmosphere.

Sixty-seven correspondents ascribed no value to elevation whatsoever.

Nineteen ascribed benefit to the absence of organic matter. We do know, however, that at uninhabited elevations the germ-breeding elements of heat and moisture are not only absent and dryness and coolness present, but Professor Tyndall and others have shown that bacteria, floating in dust and attaching themselves to moist surfaces, are found only at low altitude and more or less high temperature.

Dr. Talbot Jones, St. Paul: "All the organic processes are much more active in such situations than in those of less elevations. There is increased and coincident construction and destruction of the tissues, and the processes of digestion, respiration, sanguification, and assimilation are increased, which promote body gain and strength.

"It is far more rational to assume that the resultant increased vital energy and health promotion observed in these elevations are more important factors in the arrest of phthisis than a mere aseptic condition of the atmosphere."

Dr. H. I. Bowditch, Boston (referring to elevation, sepsis, and reduced pressure of air-column in one): "Theoretical entirely, as I deem them, and therefore my opinion from actual experience, or from the *proof* offered by others, is not worth a straw. Ergo, I shall not pretend to give it as containing even the smallest quantity of truth."

Dr. Deering J. Roberts, Nashville, Tenn.: "Altitude, in addition to purity of atmosphere, gives a surety of freedom from subsoil moisture."

Dr. H. V. M. Miller, Atlanta, Ga.: "These advantages could be secured in mid-ocean, on broad prairies, or sandy deserts."

Dr. Sterling Loving, Columbus, Ohio: "Here we are obliged to consider carefully the question of the presence or absence of malaria."

Dr. William T. Plant, Syracuse, N. Y.: "I incline to the 'fresh air in abundance' theory rather than to the aseptic."

Dr. L. P. Yandell, Louisville, Ky.: "Because less dampness, less miasm is likely there."

Dr. S. M. Bemiss, New Orleans: "Abundant fresh air in motion. Know nothing of 'aseptic' air in consumption. Butchers are very exempt."

Is there reason to believe that *reduced pressure of the air-column*, such as exists at considerable elevations, has any decided therapeutical effect upon the organism, independent of the purity or other qualities of the atmosphere?

We know that at an elevation of three and a half miles

the air is twice as rarefied as at sea-level, four times at seven miles, sixteen times at fourteen miles, etc.

The surface of a man's body may be said to be sixteen square feet, and the pressure of the air-column upon a square centimetre of surface, at mean barometric pressure, 1,033 grammes. At an elevation of 6,000 feet, the surface of the human body is relieved of a pressure of three pounds to the square inch, which is equal to 7,000 pounds for the whole man.

The respiratory mucous membrane of the lung has been calculated by Lieberkühn to be 1,400 square feet. Whether at high altitudes the reduced pressure leads to more *frequent* or more *profound* inspirations; whether *more or less oxygen* is taken in during inspiration, on account of the fact that there is less oxygen in a given measure of air—these questions are clearly individual. The attempt of the human organism to adapt itself to the change is: That at first there is *increase of functional activity*, both as regards the heart's action and respiration; and that this is in time followed by *organic changes*, manifested in the heart by regular rhythm and strong impulse (normal hypertrophy), and in the lungs by expansion involving the thorax.

Drs. Williams and Weber, of London, have published some observations in reference to heart's action and lung expansion at altitudes. Dr. Denison, of Colorado, has made similar observations. The temporary and lasting effects of reduced pressure will no doubt soon be noted and recorded in hundreds of cases.

The great majority of my correspondents attributed *no* beneficial effects to reduced pressure of the air-column.

Dr. I. N. Danforth, Chicago: "In some cases it appears to be of benefit, and in some it is injurious; in most cases negative."

Dr. P. Gervais Robinson, St. Louis: "It is reasonable, in my opinion, to suppose that in high elevations some benefit may accrue in *incipient catarrhal phthisis* from the greater 'besoin de respirer,' which, by more frequent and more forcible inspiration, would tend to expand thoroughly the lobules affected."

Dr. Alonzo B. Palmer, Ann Arbor, Mich. (referred to his "Practice of Medicine"): "But no condition has as much influence upon phthisis as *elevation above the sea-level*. . . . The most marked condition of an elevated situation is the rarity of the air and the diminution of atmospheric pressure."

Of the effects: "Deeper and more rapid respiratory movements."

Dr. G. M. Garland, Boston: "Reduced air pressure does have an effect upon the organism, sometimes favorable, sometimes otherwise, irrespective of purity. The efforts at respiration are more vigorous and the lung is more thoroughly ventilated; the chest expands in girth at high elevations."

Dr. N. S. Davis, Chicago: "Yes, it causes, unconsciously, greater activity in the respiratory muscles, to expand the chest, to get more air into it."

Dr. Beverley Robinson, New York: "May lessen tendency to certain visceral hyperæmias—even though it augments congestion of bronchi."

Dr. Deering J. Roberts, Nashville, Tenn.: "In its rarity it seems to have the effect of a stimulus—especially to the nervous system."

Dr. H. D. Didam, Syracuse, N. Y.: "In incipient cases with bronchial catarrh in apex, a mountain elevation and proper instructions will, *by securing chest expansion*, do good."

Dr. M. F. Coomes, Louisville, Ky.: "The only special claim for a great elevation is that the rarity of the atmosphere will necessarily expand the lungs more thoroughly than that of ordinary elevations; and, as a natural consequence, would tend to prevent further deposit of tubercular matter. The respiratory effort is certainly increased, and, of course, with it the circulatory system is rendered more active; appetite is increased, and digestion as well."

Dr. H. V. M. Miller, Atlanta, Ga.: "The leading mark of the tuberculous diathesis is confined breathing space, often a congenital narrowness of the chest, insufficient lung expansion. As tubercles begin to be deposited, they impinge more and more upon the breathing space, and lessen day by day the office of the lungs in the formation and purification of the blood and its elements. The progress of the disease is measured by the progressive solidification of the lung, and no means of cure deserves confidence which does not seek to prevent or remove this impairment of an essentially vital function. This fact is recognized when patients are directed to exercise the voluntary muscles subservient to respiration, to employ vigorously the muscles attached to the chest, that they may be developed and the chest expanded, exercising the voice or the spirometer, swimming, rowing. All, it is hoped, may and doubtless do become beneficial; but how little time can be devoted to one or all of these!

"Each thousand feet of elevation above the sea-level, it is estimated, removes one thousand pounds of atmospheric pressure from a man's body, and the rarity of the air is in like proportion greater, so that with every breathing effort there is corresponding increase of expansion of the lungs to supply the needed oxygen. This is an exercise which is continuous, sleeping and waking, and, theoretically, ought to lead to the development or restoration of greater breathing space, and all the important physiological results dependent upon it. Experience has demonstrated the value of the practice, if not the correctness of the explanation. A large and increasing number of instances where, by the spirometer, by actual measurement of the chest, the removal of tuberculous deposits already existing, increases of bodily weight and vigor, and restoration to health, have shown that a longer or shorter sojourn in elevated regions is extremely useful."

2. HUMIDITY.

The amount of moisture suspended in the air is the most important constituent of climate. When the air is saturated, we say it contains one hundred per cent.; fifty per cent. is one half saturation, and all humidity is recorded with reference to its percentage.

A few facts are to be borne in mind:

1. That the air is capable of holding moisture according

to its temperature. Heat expands air and increases its capacity for suspending moisture.

2. That humidity decreases with increasing elevation, on account of vapor being diffused into greater space. Or, if we only remember that the greatest amount of moisture is over its source (large bodies of water, the ocean) and near it, at the sea-shore, and the farther we get inland the farther are we removed from the source, it will be agreed that my statement of this fact is the correct one, namely:

Humidity decreases with increasing distance from the chief sources of moisture, whether that distance be horizontal or vertical, far inland or at high altitude.

Where, far inland, position and elevation above sea-level co-exist, the distance from great bodies of water is the number of miles overland plus the elevation above the ground; in other words, the altitude is simply a vertical addition to the horizontal distance.

As to dryness as a potent factor in a suitable climate for the majority of consumptives, the question as to its potency was affirmatively by nearly every one, with some qualifications as to degree and as to the class of cases in which a moderate degree of moisture was desirable.

The fact (which to my mind is the key-note to the question) that moderate moisture is desirable only because we look for *equability of temperature*, and can not have *equability without some moisture superadded*, seems not to have attracted the attention of any one.

Dr. Charles Denison, Denver, Colorado: "Yes, decidedly (see chapter on "Humidity," "Rocky Mountain Health Resorts," pages 60 to 67). Practically, experience sustains this positive answer, and, theoretically, I think it would be generally admitted by observant physicians that the increased proportion of moisture exhaled to that inhaled—i. e., the increased facility with which impurities are thrown off through increased exhalation—would be a remedial agent of no mean value in most chronic lung diseases."

Dr. Alfred Stillé, Philadelphia: "So far as I know, tubercular consumption is almost unknown in the driest climates."

Dr. J. Solis Cohen, Philadelphia: "The point upon which I desire to lay most stress is this: That sea air should be rigorously avoided as soon as there are any signs of softening in the lungs or ulceration in the larynx. My habit has been to study carefully each individual case; to notice how the different seasons and atmospheric conditions affected the patient when at home, and to endeavor to find a climate corresponding with the indications thus obtained. I have thus found great divergence of conditions in different cases, which will, I think, account for the divergence of professional opinion which we notice. An important point of inquiry would be as to the health of the children of consumptive parents, born or bred at the different resorts, supposing, of course, the parents to have permanently located; otherwise the statistics would be valueless. I have had quite a number of these, now young adults, sent to me of late years, with different forms of laryngeal and pulmonary complaints, from Minnesota. *Sea air before softening; mountain air after softening.* Do not recommend sedative climates, but consider dryness a potent factor, and, in the

majority of cases, a cold temperature; but this must be governed by the comparative comfort of the patient under similar conditions at home (New Mexico, Colorado, California). Sent patients to Lakewood, N. J., lately; to Aiken, Southern California, Mexico, and the Adirondacks even in winter. A patient should make arrangements for permanent residence in whatever locality he finds his health the best."

Dr. H. von Sweringen, Fort Wayne, Ind.: "The lungs, we know, are constantly giving off aqueous vapor. It is a fact in consequence that, when the atmosphere is saturated with moisture, its power of conducting off this vapor will be proportionally diminished, and that an accumulation of fluid may thus take place in the lungs. The air may also be so dry as to have an increased capacity for moisture, and to carry off the expired air or vapor with unusual avidity; in either of these cases the excretions from the lungs will be materially influenced, whether to the benefit or disadvantage of the consumptive patient is the question which you are endeavoring to settle among other inquiries. With you I am inclined to favor a *dry* climate. We frequently observe remarkable changes occur in the character of a cough, at the breaking-up of a frost; in some cases the expectoration will be checked, and in others promoted by a sudden change from a dry to a moist atmosphere. I have no doubt that in some cases the rapid transition from moisture to dryness will occasion a marked effect upon consumption, and, again, that others, confined in artificially warmed apartments, are benefited by evaporating a certain amount of water whenever the external air has become excessively dry."

Dr. H. I. Bowditch: "*Most certainly.* I have removed persons (and every day prescribe the same for persons consulting me) from houses on low, damp land. Even houses with damp cellars should not be lived in."

Dr. Frederick I. Knight, Boston: "Every case has to be considered on its own merits. I have had many cases of early disease make wonderful recovery in Colorado."

Dr. James T. Whittaker, Cincinnati, Ohio: "Dryness is a most potent factor, because the specific cause of the disease develops best in, and absolutely requires, moisture."

Dr. H. D. Didama: "Not the dryness *per se*, but because it is usually associated with sunshine."

Dr. G. Baumgarten, St. Louis: "Yes; but, when united with considerable altitude, the effect upon certain persons—briefly described as nervous—is very bad."

3. TEMPERATURE.

In the relation of temperature to consumption we have two facts to consider: *a.* The mean monthly and yearly degree of heat, which gives us an idea as to whether the climate may be called hot, warm, cool, or cold. *b.* Monthly and annual range (difference between the very lowest and the very highest readings which have occurred in that time), from which we gather knowledge as to the stability, the *equability of temperature*; and in connection with this we note diurnal ranges as indicating daily fluctuation.

Broadly speaking, it may be said that heat and warmth are intimately associated with moisture, and cold and coolness

with more or less dryness. For this reason, no climate should be spoken of as being hot or cold except in connection with other elements. "Hot" and "cold" relate to sensations, and are not a *constituent* of climate. Granted that equability is the *prime* beneficial element in certain cases; then, at least, let a locality be selected where, as between equability and relative humidity, the lowest degree of humidity attainable is associated with reasonable equability of temperature, and *not great equability with excessive moisture*, which, as a rule, go together.

It has been abundantly proved by Dr. C. T. Williams,* and since corroborated by experiences of others, that, "taking collectively all forms and degrees of phthisis, the dry climates are the most likely to arrest the disease."

The tolerance of the lung against variously tempered air is much greater than is commonly supposed. Heidenhain has shown that this tolerance ranges over one hundred degrees. As in the effects of altitude, this is likewise in a patient a matter of accommodation, and is that which is generally called *acclimatization*.

Dr. Charles Denison: "Equability is too much associated with dampness of atmosphere. I consider equability of temperature a valuable climatic attribute in some instances, while it is an almost impossible constituent—because opposed to elevation and dryness—in the health resort most suitable for the majority of first-stage consumptives.

"You probably ask, In what instances is an equable and rather moist climate desirable? In a general way I would reply, In irritable heart, irritable cavity, in extensive catarrhal phthisis, and especially in neurotic patients if progressive softening, advanced age, or being in the female sex, augur an unfavorable issue.

"As the most desirable type of an equable temperature climate, I refer to such portions of Southern California as Los Angeles (Sierra Madre Villa near by, low elevation, 1,500 feet) and Santa Barbara (Ojai Valley not far distant, containing several places of moderate elevation). The bountiful supply of sunshine, and the natural protection from north winds, furnished by the coast range, together with a temperature which invites to an out-door life at all seasons of the year, make the last-mentioned region an especially favorable locality for the serious or irritable cases enumerated above."

The following atmospheric constituents, with their variations, are dependent upon, and, so to speak, the offspring of pressure, temperature, and humidity:

1. Winds—dependent upon pressure and temperature.
2. Intensity of sunlight—upon pressure and humidity.
3. Electricity—upon humidity and temperature.

And out of the relations of these last three to the first result: Precipitation, the production of ozone, and mechanical and organic admixtures of the atmosphere.

Both advocates of equability and of dryness justly claim *abundance* of sunlight, a majority of clear days in the year. But the *intensity* of the sun-bath is not by any means the same in equable and dry, elevated climates. In equable climates the sun's rays are obstructed by moisture plus the

* Lettsoman Lectures for 1876. "The Influence of Climate in the Prevention and Treatment of Pulmonary Consumption."

greater density of the atmosphere; at altitudes moisture is more than half reduced (often one quarter), and the density of the air gives way to rarity. Hence, the sun's rays have ready access to the earth's crust, and in mountainous countries this crust presents an increased surface in the up-turned sides of the mountains. Our knowledge of the effects of the above constituents on the human organism is not such as to have required any questions or answers.

Next to the constituents of climate, which are dependent upon conditions of soil and atmosphere, the artificial admixtures of the air (as distinguished from moisture, a normal ingredient) are inorganic and organic. Inorganic as dust, organic as animal and vegetable ferments. Dust is chiefly coexistent with dryness, while germs flourish in the combination of moisture and heat.*

Subsoil moisture is the most prominent cause of the development of phthisis. The credit of establishing this fact is entirely due to Professor Henry I. Bowditch, of Boston, who has also established the lasting fact that "artificial drying of the soil by subsoil drainage, etc., has actually caused a decrease of the death rate by phthisis in places where such sanitary measures have been adopted.†

Subsoil moisture may simply be classed as furnishing one of the admixtures of the atmosphere, in my opinion, in this: that its ill effects arise from furnishing surplus moisture to the lower strata of the atmosphere. Again, in the presence of persistent heat, it is the breeding ground for micro-organisms. The facts may be formulated thus: when *dry*, the soil furnishes the mechanically irritating dust; when *moist*, moisture, gases, and micro-organisms.

SEA- AND MOUNTAIN-AIR.

In accordance with the natural divisions of our globe into sea and land, climates are often spoken of as *marine* and *continental*. A limited diurnal and annual range of temperature is characteristic of marine climates, enjoying, as they do, the equalizing influence of watery vapor; a lack of this influence and great range of temperature characterizes distances from large bodies of water.

The great element of marine climates is *equability*. The great element of continental climates is *dryness*. Elevation (our third constituent) may be found upon islands in mid-ocean, as well as far inland; this constituent, therefore, may be common to marine and continental climates.

The chief causes of consumption—subsoil moisture and micro-germs—are found at considerable distance from lowlands and the wholesale aggregation of higher living organisms—the human race. This distance by which an aseptic condition of the atmosphere is insured may be horizontal, out upon the *high seas*; or vertical, up among *mountain plateaus*. I put it down now, as a maxim, that the ultimate aim of all phthisical patients should be to reach high alti-

tudes. Some cases are fit for it from the start; others require lesser altitude at first, while *both* require dryness; still others have irritability of sensation (in skin and mucous membranes), and low-grade inflammations as so prominent a feature of their case that they should first go through the preparatory school of equability of temperature. My argument is this:

1. That the vast majority of consumptives are tubercular with accompanying inflammation, and not *vice versa*.

2. That tubercular consumption is a product of the tropics; of the combination of heat and moisture, which encourage venous stagnation (hyperæmia) and embolism of lung capillaries.

3. That, therefore, the two enemies to be avoided are persistent heat and excessive moisture.

4. That this avoidance requires distance from tropical latitude on the one hand, to avoid heat; and distance from the father of moisture, the ocean, on the other.

5. This distance takes us inland, either into the middle of our continent, or up into the frigid zone. The greater the distance the better.

6. The frigid zone combines excessive cold with fluctuations of temperature and some moisture—the progenitors of acute inflammation of the air-passages.

7. That, if the *horizontal* distance be not great enough to keep out of additional danger, we must look for the extension of distance in the *vertical* direction—at mountain-heights—at *far inland high altitudes*.

A great factor in the equalization of temperature is the Gulf Stream. Its effects on our coasts (Japanese current) are felt in Alaska, Puget Sound, and parts of California.

SEDATIVE AND TONIC CLIMATES.

A sedative, soothing, so-called "mild" climate has *equability of temperature* as its chief pillar, and may be either moderately dry and moderately equable, or very equable and very moist. The reigning temperature may be hot, warm, or cool. Such climates exist on numerous islands in the temperate and torrid zones—Madeira, Canaries, Azores, Bermudas; at peninsulas in southern latitudes, of which Florida is an example; and at the sea-coast of more or less southern latitude, where the effects of the Gulf Stream are felt—coast of southern California.

A tonic, sthenic, so-called "invigorating" climate, the effects of which are also denominated as "bracing," has *dryness with more or less elevation* as its pillar, and may be moderately dry or very dry, far inland without elevation, or at moderate or high altitude. Such climates in southern latitudes must have considerable altitude to insure a reasonable degree of coolness, while in northern latitudes low, medium, and high altitudes are cool, and even cold. In no latitude of the temperate zone is equability of temperature one element of a sthenic climate, because it presupposes moisture. In our country sthenic climate is represented by all the medium and high altitudes of North Carolina, Georgia, Tennessee, Colorado, New Mexico, Arizona, Texas, and California, and the far inland States in northern latitude—Minnesota and adjoining sections.

These terms sedative, tonic, etc., have no especial sig-

* "Floating Matter of the Air in Relation to Putrefaction and Infection." By John Tyndall, F.R.S., 1882.

"Consumption in New England and Elsewhere, or, Soil Moisture one of its Chief Causes," Boston, 1868.

nificance. It is the old fault of calling climates by the sensations they convey, instead of defining their constituents of barometric pressure, temperature, and humidity.

For the same reason the answers to the next question—"To what particular region or health station do you direct your patients suffering from pulmonary consumption?"—will be attached to the foregoing.

NEW ENGLAND STATES.

Dr. C. P. Frost, Hanover, N. H.: "Sedative climates not suitable for consumption. I prefer northern Georgia or California. In the proper season, the Adirondack region seems beneficial."

Dr. Henry I. Bowditch, Boston: "I have no doubt the sea-coast of New England, and possibly of the Atlantic still farther south, is *always injurious to the consumptive at any period of the disease*. I have no doubt that *early stages*—say, perhaps, crackling under one clavicle, and a little difference on percussion—are sometimes *wholly cured by a permanent residence in Minnesota* or the mountains of Colorado. I think Fayal, or some island in the ocean, has been at times of service. . . . I prefer the so-called 'sthenic' climate, and I think my experience sustains me. . . . I decide very frequently according to the social relations as well as the disease. The fact that a person knows by experience, or has friends, or can do business in a certain place, will induce me to choose a northern or southern climate. I send now, *generally*, to Colorado, or some of the high places in the West or Southwest. I tell a patient he must stay summer and winter, or, in other words, must live where I send him. If he returns to the East, he will very frequently fall back and die—even if he appear well of all general and local signs when examined on his return. As to general results: *Good* if sent when few signs, and the after-life be spent in the new place for many years, or, if possible, for life. *Almost certainly bad* if sent when gurgling or strong bronchial respiration, etc., exist, intimating severe lesion of the lung."

Dr. R. H. Fitz, Boston: "My view at present with regard to consumption and climate is, that in the earlier dates uniform temperature—cool, rather than warm—high elevations, and dry air, with physical and mental comforts, are essential. In the advanced stages, uniform temperature—warm, rather than cool—with moderately moist air, gives comfort to most patients."

Dr. G. M. Garland, Boston: "I should prefer a sedative climate where there is a dry, hard cough, with a tendency to hæmorrhage, but before the disease manifests many physical signs of destruction of lung-tissue. Winter in Florida; summer in the North or West (Kansas or Colorado)."

Dr. Charles H. Fisher, Providence, R. I.: "The higher and drier the locality above sea-level the better, *providing always* the most equable climate, the most uniform mean temperature (between 60° and 70° Fahr.), and allowing constant respiration of open air. . . . Sedative climate for advanced cases; sthenic climate for incipient ones—parts of Minnesota, Colorado, California. Advanced cases, northern latitude for summer, southern for winter."

(To be continued.)

DOUBLE IRRIGATION AND DRAINAGE TUBES.

By HENRY O. MARCY, M.D.,

BOSTON.

I devised and had made for me in 1880, by the Davidson Rubber Co., of Boston, double tubes of pure gum, prepared in glass molds in a manner similar to the rubber catheter.

My purpose was to furnish a double tube of flexible material, at a moderate cost, and thereby secure the advantages of irrigation by a continuous current, through an instrument safe in its application.

These were of the same perfect finish and flexibility as the catheter, and varied in diameter, French scale, from No. 18 to No. 40, and in length from fourteen to twenty-four inches.

They were exhibited in the Surgical Section of the American Medical Association in 1881, and a brief statement of my experience in their use was published in the Transactions for that year. They were also presented to the International Medical Congress held at London in 1881, and are described and figured in the Transactions.

Since this time they have been widely known to the profession, and to a considerable degree are in general use. The purpose of this brief paper is to call attention to the fact that Messrs. Tiemann & Co., of New York, have improved the smaller varieties of these tubes (those numbers suitable for use in the male bladder) by furnishing a probe point and the "velvet eye" peculiar to their excellent catheters. This enables the instrument to be made smaller, since the direct current requires only a small stream. The effluent tube is relatively larger, and thus overstrain upon the bladder is prevented.

At my suggestion, attachments have been made so that the tubes may be lengthened at will. As now made and sold by Messrs. Tiemann & Co., these tubes appear very nearly perfection, and are furnished at a much less price than formerly.

They are of the same easy introduction into the bladder as the now universally used rubber catheter. As a rule, the patient requires no assistant. The ordinary fountain syringe is filled with the fluid desired, and placed at a height usually only sufficient to secure the continued steady outflow after the bladder has been somewhat distended. Pain or discomfort indicates that the hydrostatic pressure is too great. The prolonged effluent tube conducts the fluid into a receptacle provided therefor, while the patient is usually most comfortable in the semi-reclining position, an easy-chair of almost any description serving well the purpose.

FIG. 1.

After the patient becomes accustomed to the irrigation of the bladder, he gladly avails himself of the newspaper or an entertaining book, and passes, with very little discomfort, the half-hour usually required to give the douche as thus applied. A continued experience of three years in a very considerable number of cases of cystitis, both acute and chronic, leads me to feel that the value placed upon this means of medication in my earlier publications was not overestimated.

In cystitis dependent upon retention of urine from enlarged prostate, although not curative, relief is very great. In a very considerable number of cases the micrococci and bacilli universally accompanying, if not causing cystitis, have disappeared. Water used at a temperature as hot as comfortable, the heat-point varying considerably with different individuals, has been used, but more often a weak antiseptic solution of boric acid, carbolic acid, or Listerine has been employed.

The secondary effect of heat has proved very efficacious in cases of hæmorrhage from the bladder; in one intractable case the current was continued without interruption for more than twenty-four hours; however, clots in the bladder are likely to be a source of trouble from the occlusion thereby of the efferent tube. Usually in severe cases of cystitis the douche has been used once or twice daily, and continued about half an hour.

FIG. 2.

The larger tubes are, perhaps, best as made in their original form (see Fig. 2).

The tube of fourteen inches, size No. 40, is a safe and effective instrument for the cleansing and disinfecting of the uterine cavity in puerperal septicæmia. The caliber and fenestræ are of considerable size, and allow of the easy removal of decomposing débris, while the character of the tube reduces the danger of injury to the organ to the minimum.

In strictures of the rectum or inflammatory conditions of the pelvic organs the relief and benefit of the continued rectal douche have been very marked. In these cases the tube enters the colon, and the hot water is siphoned in without strain upon the intestinal wall at a point above the constricted or inflamed part. Not only is the large intestine emptied of its gas and contents, and the tenesmus and pain removed, but the prolonged effect of the continuous current is very efficacious in reducing the congestive and inflammatory processes (e. g., dysentery).

The comfort and advantage have been equally marked after various pelvic surgical operations, where gaseous distensions of the colon are often so troublesome.

The use of the double current through such a soft, flexible tube renders it easy and effectual to cleanse the pleural cavity in empyema, to wash out long, irregular sinuses, deep gun-shot wounds, where necrosis of tissue must follow the track of the bullet, and where shreds of clothing, small pieces of bone, or other extraneous materials are retained.

In nutritive enemata I have felt that a very considerable gain has followed by the introduction of the fluids thus high in the transverse colon, and can but recommend their use for further trial.

The larger and longer tubes are of easy application for the evacuation of the stomach. A tube of this kind and an ordinary rubber syringe are all that is required for the speedy and effective emptying of the stomach; artificial feeding is also by this means easily accomplished. This we have had recourse to in a number of instances with children as well as adults.

It is usually well to lengthen the efferent end, or both, by connections with rubber tubing, as thought most convenient.

Correspondence.

LETTER FROM BOSTON.

THE STATE HOSPITAL AND ALMSHOUSE AT TEWKSBURY.

Boston, May 29, 1883.

UNDER the head of "Miscellany" you have several times referred to the "Tewksbury Investigation." Let me occupy a little more space on the subject than you have heretofore devoted to it. There has for a long time been a feeling in the minds of those who have been brought into official relations with the hospital at Tewksbury that matters were not conducted as they should be; and as long ago as 1874 the late Dr. George Derby, at that time secretary of the State Board of Health, had a conversation with one of the best hospital managers in the country, and told him what the Board of Health wanted to do if they could get control of the institution; and asked if he, the manager, could recommend any young man, familiar with hospital management, who would take hold, with the support of the board, and make the institution a credit to the State. Unfortunately, the death of Dr. Derby, which took place shortly afterward, prevented the idea from being carried into execution.

In 1879 the Hon. Thomas Talbot, in his inaugural address to the Legislature, recommended several changes looking toward the reduction of the number of the State commissions. One change was the abolishing of the Boards of Health and of Charities, and the establishing of the Board of Health, Charity, and Lunacy.

Soon after this, Mr. F. B. Sanborn, the present secretary of the board, preferred charges against the management of Tewksbury. The investigation was private, and the whole matter was thought by some to be "whitewashed"; yet good was accomplished, for through the investigation reforms were instituted; and since then affairs have been conducted in a much more satisfactory manner, and no complaints were heard till His Excellency, Governor Butler, in his inaugural address last January, took occasion to speak in a highly disparaging manner of the various State charitable institutions; and later on, when

the appropriation bills for their support came before him for action, he vetoed them, and made such charges against the Tewksbury State Hospital and Almshouse that the Legislature appointed a special committee to investigate this institution.

This legislative committee began its labors on March 30, 1883, Governor Butler appearing as the prosecuting officer, while the trustees of Tewksbury were represented by E. P. Brown, Esq., a young lawyer of marked ability.

A detailed account of the testimony would be too long. I will therefore only touch upon that interesting from a medical point of view.

One witness testified that hundreds of babies' bodies were sent yearly from the Tewksbury poor-house to the Harvard Medical School to be used as subjects for dissection; that he himself had repeatedly dissected such bodies; that the students bought the bodies surreptitiously from the janitor and carried them home; that animals were dissected on the same table with the human subjects; and that the remains of both were placed in a common receptacle and buried in the same pit.

The rest of the testimony was directed toward the mismanagement of the superintendent in allowing bodies to be packed in boxes at night and carted off to the medical schools, or to practitioners who wanted material for dissection. The resident physician was charged with the improper performance of craniotomy. Supplies and the effects of paupers were alleged to have been purloined by the family of the superintendent.

Before all his evidence was in, the Governor, for reasons best known to himself, removed the trustees of the institution, and placed it under the control of the State Board of Health, Lunacy, and Charity; and recommended the dismissal of the former superintendent, and specified whom he would consent to have appointed in his place.

Acting under legal advice, the board above named assumed control, but not until quite a voluminous and spicy correspondence had passed between the secretary of the board and His Excellency, in which correspondence, let me say, the Governor did not come out with flying colors.

One of the first acts of the board, on assuming control, was to send one of their number, Mrs. Clara T. Leonard, a lady whose experience in such matters is well known, to examine the institution and report the true state of affairs. This she did, and her report was, in the main, favorable to the management of the institution. The report itself was a masterpiece, and I recommend it for the perusal of all interested in the subject. The board was obliged to declare the office of superintendent vacant, as the incumbent had failed to file a bond as prescribed by law. At present a member of the board is acting in that capacity, but the office will be filled when the Executive Committee find a suitable man. It is reported that they intend to appoint a physician; but, in order to get one fit for the responsibilities of the position, a much larger salary will have to be paid than has been heretofore. At present there is no money appropriated for the carrying on of the institution, the Legislature favoring one sum, the Governor declaring it too much, and that he is willing to "run" the institution himself for a much less amount. Supplies are bought on credit, and it is safe to say funds for the payment will be forthcoming in due time.

The testimony for the defense began on Monday, May 14th, but this I will leave for another letter. The general impression is that the investigation will be the ground upon which the Governor will raise the issue for his election next fall. The best campaign document that could be sent out to controvert the assertions made by His Excellency would be the report of Mrs. Leonard, spoken of above.

Book Notices.

Hand-Book of the Diagnosis and Treatment of Diseases of the Throat, Nose, and Naso-Pharynx. By CARL SEILER, M. D., Lecturer on Laryngoscopy at the University of Pennsylvania, etc. Second edition, thoroughly revised and greatly enlarged. With seventy-seven illustrations. Philadelphia: Henry C. Lea's Son & Co., 1883. Pp. 295.

The first edition of this little text book has already been reviewed in this journal, and received the favorable notice to which its merits entitle it. We are glad that it appears again in a second and enlarged edition, for it is one of the best of the practical text-books on this subject with which we are acquainted. The present edition has not been issued without considerable work on the author's part, especially in the department of diseases of the nasal cavities, and for this reason the size of the book is increased; but its eminently practical character has been maintained. Many new illustrations have also been introduced, a Case Record-Sheet has been added, and there are a valuable bibliography and a good index of the whole. For any one who wishes to make himself familiar with the practical management of cases of throat and nose disease, the book will be found of great value.

Transfusion: its History, Indications, and Modes of Application. By CHARLES EGERTON JENNINGS, L. R. C. P. Lond., etc. London: Baillière, Tindall, and Cox, 1883. Pp. viii-69.

DR. JENNINGS is already well known to the readers of current medical literature for the interest he has shown and the study he has devoted to the question of transfusion, and the present little volume is a *résumé* of what he has previously written. He believes in the use of a saline fluid in preference to human or other blood, and gives the formula for its preparation. He has also invented a very safe, simple, and effective syringe with a sharp needle which he introduces into the vein of the patient to be operated upon; and to the consideration of these two elements of the operation, and the objections to the older methods, the book is chiefly devoted. He has also been to considerable pains to collect a very complete bibliography of the subject, covering twelve pages.

BOOKS AND PAMPHLETS RECEIVED.

Labor and Capital. By Edward Kellogg. New York: John W. Lovell & Co. Pp. xxvi-17 to 374, inclusive. [Lovell's Library. Price, 20c.]

The Principles and Practice of Medical Jurisprudence. By the late Alfred Swain Taylor, M. D., F. R. S., etc. Third edition. Edited by Thomas Stevenson, M. D. Lond., F. R. C. P., Lecturer on Medical Jurisprudence and on Chemistry at Guy's Hospital, etc. Philadelphia: Henry C. Lea's Son & Co., 1883. 2 vols., pp. xx-727; xiv-657.

Notes of a Case of Enteric Fever which had Two Relapses, with an Unusual Prolongation of the Interval between the First and Second Attacks. By Robert W. Forrest, M. D. [Reprint from the "Glasgow Medical Journal."]

Tubercular Cerebro-Spinal Meningitis. By J. T. Eskridge, M. D., etc. [Reprint from the "Journal of Nervous and Mental Disease."]

ANTI-VIVISECTIONISTS.—Sir Spencer Wells invented a term for the anti-vivisectionists, in his *Hunterian oration*, that will establish his reputation in a new direction; he denominated them "misanthropic zoophilists."—*Med. Annals.*

THE EFFECT OF COLLEGE LIFE ON THE HEALTH OF
WOMEN.

In view of the increasing numbers in which young women are availing themselves of the means open to them of pursuing courses of study and of after-life analogous to those followed by college-bred men, the question is becoming more and more interesting as to the effect such a career has upon their bodily health. This question has indeed been contemplated by many who have had it brought to their attention, but as a general thing it has not been discussed by them in the light of any considerable collection of facts. In an article published in a recent number of "Education," a summary of which we find in the "Boston Journal," Mr. L. H. Marvel gives a number of data gathered by means of correspondence with instructors in some of the principal educational institutions that are open to women.

Information was asked in answer to the following questions: 1. How does the health of young women who enter the institution compare with the health of other young women of the same age and of like social position? 2. How does the health of those who graduate compare with the health of the same persons on entering college? 3. In those institutions where both sexes are admitted, is there any marked distinction in the effects of college life upon men and upon women?

The summary to which we have referred does not give the facts brought out by the first question, if any there were. It may be doubted, indeed, if college preceptors are in a position to reply to such a question with a much fuller knowledge of the facts than common observation would supply to others. Concerning their own pupils, it is true, they are doubtless able to speak with an approach to precision, but we fail to see by what means they are to estimate the health of other young women with sufficient accuracy for the purposes of the comparison.

The answers generally given to the second question were to the effect that young women are apt to go through their pupilage without impairment of health, unless in the case of those who try to accomplish more work than the curriculum embraces, or than the teachers approve of, and of those whose physique has already been impaired by "the demands of society." It was stated by many, indeed, that the body as well as the mind was strengthened by the course.

In regard to the matter covered by the third question, there seems to have been some difference of opinion. While the principal of the Normal School at Salem, Mass., thinks that on the average young women can not safely do as much mental work for a considerable period as young men, the president of Madison University reports that the young women achieve their

tasks with less labor than the young men, and, although in no wise falling behind the latter as scholars, are, on the whole, in better health.

The mortality rates among graduates of various colleges are given, covering a period of thirty years. From these it appears that, of the graduates of Mount Holyoke Seminary, representing the schools for young women, only 10.39 per cent. died during the term of years mentioned. Only one other institution, Williams College, showed a lower rate, 10.12 per cent., while the proportion among Harvard men (exclusive of the "war mortality") was 11.52 per cent.; that of the Yale alumni 13.42 per cent.; and that of Dartmouth graduates 16.83 per cent. It is to be hoped that Mount Holyoke is a fair example of the better class of those institutions in which women are educated.

There is an opportunity, it seems to us, for the various medical colleges for women to contribute materially to the elucidation of the points covered by queries like those alluded to. Although those institutions can not deal with the large numbers of pupils that are to be found in the academic schools, the accuracy with which their instructors could make their observations would more than counterbalance the numerical deficiency.

AUTOPSIES FOR LEGAL PURPOSES.

An anonymous correspondent of the "New York Times" calls attention to the case of a soldier, a raw recruit, who was accidentally killed by a bullet wound at a rifle range, he having incurred the shot by carelessly stepping out from behind the target while the firing was going on. The writer states that a post-mortem examination of the soldier was made, by order, as he avers, of the Surgeon-General of the army. And he then proceeds to descant upon the injustice of ordering an autopsy in a case of manifest accident without the consent of the dead man's friends, or rather, as he really puts it, without the man's own consent. He further argues that no one would think of performing an autopsy on the body of a soldier killed in battle, and draws a parallel between that sort of death and the incident in question.

Now, all this is very touching, and doubtless it reflects the natural feelings of a large-hearted person; but, before rushing into print with a grievance, whether it be one's own or one adopted for the occasion, it is well to look at both sides of the matter. We are not convinced that our friend has done so in this instance. He does not state what means he has of knowing the precise facts in the case, and, as he chooses to conceal his identity, his readers are left in the dark as to those means. His argument they can follow, to be sure, perhaps in utter forgetfulness of the fact that the best of arguments is but a mockery unless founded on a basis of strict fact. It is quite possible that there was an element in the case that made it the duty of the post surgeon to satisfy himself as to the cause of death beyond legal quibble. Indeed, something of the sort is almost certain, for nothing is clearer than that the gentlemen of the army medical corps, no less than the line officers, are scrupulously tender of the rights of the enlisted men, especially

so sacred a right as that of the decorous disposal of their dead bodies.

There are many circumstances that may make the performance of an autopsy a duty, although they may not be apparent to a layman. In this very case, even taking the writer's version, it is obvious that the parallel between a violent death at the hand of a comrade, however manifestly accidental, and a death met in battle, by a shot from the ranks of the enemy, is not beyond criticism. Some malicious tongue might assert that the fatal shot was so intended, and in that case a judicial inquiry would probably be the result. Such an investigation would be sadly defective, if it did not elicit proof positive of the cause of death. In law, whether civil or military, a mere impression is not competent evidence, however general it may be, or however well founded it may appear, unless all means of corroborating or of dispelling it have been exhausted. In view of the chance that such an investigation would be called for sooner or later, it would have been a manifest dereliction of duty on the part of the medical officers concerned in this case if they had not taken all possible precautions to facilitate the course of justice. And it should not be forgotten that it is not alone the primary sufferer, but also the accused, or he who is under a liability to be accused, that should enjoy all available co-operation in the establishment of his rights—the right to a proof of innocence being as inalienable as the right to prove an injury.

THE CLIMATIC TREATMENT OF CONSUMPTION.

In this issue of the journal we publish the first part of a notable contribution to the study of an exceedingly important question—Dr. Tyndale's article on The Climatic Treatment of Pulmonary Consumption. During the last few years we have published several valuable papers on the same subject, especially those by Dr. Talbot Jones, of Minnesota, Dr. Geddings, of South Carolina, and Dr. Kenworthy, of Florida. Each of these gentlemen wrote in the light of extensive personal observation in a field differing decidedly in climatic features from those in which the experience of the others had been gained. From their diverse standpoints a light was shed on the question that illumined not one of its aspects only, but several. As in physics two forces acting in different directions combine to impel a body in still another course, so in the march of knowledge a true advance may be the outcome of a confluence of individual movements no one of which is quite in the right line.

Dr. Tyndale will be seen to have borne this consideration well in mind, and, while he could easily have given his paper a more personal character, and thus have urged his own views more to the exclusion of others, by adopting that course he would have done far less to clear up the subject than he has chosen to do by presenting a collection of the opinions that have been formed by a great number of physicians whose opportunities and capabilities give them the stamp of positive value.

There are few questions in therapeutics of which the complexities are more difficult to unravel than this matter of the

relations of climatic peculiarities to consumption. When we take into account that the term consumption is made to cover a number of pulmonary affections differing markedly from one another, not only as to mere lesions, but as to antecedent causative changes, in short, as to the whole course of the morbid process; that the constitutional conditions are as various as could well be imagined, both as regards bodily health and as regards what is best described as the *morale*; that in one case heredity stands out as a prominent feature, while in another it plays no part whatever; that this patient is affected beneficially by a radical change of his associations, while that one pines for the scenes of his former life—when we consider all these and many other like circumstances, we may cease to wonder at the discordant sentiments that prevail as to the question of sending consumptives to one or another of the many regions that have become prominent as resorts for that class of invalids, and we may concede that St. Paul may justly boast of her cures as well as Florida. To say that either of these places, or any one of some scores of others, is *par excellence* the one to which consumptives should be sent in a routine way in crowds, is to say that the chameleon is always of a specified hue.

But, tangled as the web is, it is scarcely more unpromising to the investigator than many another therapeutical problem that has passed to its final solution; and modern methods of inquiry, taking nothing for granted, but doubting everything until it is proved, sifting facts, arranging them, and studying their interdependence, will unquestionably in the end give us a rational and available appreciation of what now seems a mass of disjointed and incongruous data.

THE MASSACHUSETTS PHARMACY BILL.

In the Massachusetts Legislature, the House Committee on Public Health has reported a bill the provisions of which are as follows: 1. The president and trustees of the Massachusetts College of Pharmacy shall annually appoint three competent persons to serve as commissioners of pharmacy. 2. After January 1, 1884, all pharmacists shall be examined by the commissioners. 3. Graduates of a college of medicine or pharmacy may carry on a druggist's business on proving that they have so graduated, and on paying a fee of three dollars. 4. The commissioners are to keep a register of all persons examined by them, and of their places of business, a fee of eight dollars to be charged for such registration, and a fee of ten dollars for the license. The latter must be not less than twelve inches square, and must be kept posted in a conspicuous place. 5. After sixty days from the time the law goes into effect (January 1, 1884) sales without a license shall be punishable by a fine of from \$100 to \$200 for each offense, and, on a second conviction, by fine and imprisonment for not more than one year. 6. The commissioners are to inspect artificial drugs and compounds, and, if they believe them to have been sophisticated, they shall order their sale to be stopped. Sales after such order shall render the dealer liable to five times the penalties before mentioned. 7. A person who can not pass the

commissioners' examination may have his business carried on by a person who can pass it.

This bill strikes us as objectionable in some respects. The provision that a graduate of any college of medicine or pharmacy may snap his fingers at the commissioners makes rather in favor of the multiplication of such institutions than in favor of an improvement in the profession of pharmacy. A suitable respect for vested rights would be secured by exempting such graduates only as are now engaged in the practice of pharmacy, leaving the commissioners to deal with all future applicants, whether graduates or not. Then, too, in regard to the inspection of drugs, we are unable to see why simple drugs should not be subjected to the same requirements as "artificial" drugs and compounds. The stress of the penalty, moreover, seems likely to fall only on those in whose possession the stock inspected may happen to have been found, leaving the manufacturer or importer unpunished. It must be admitted, however, that an active and watchful board of commissioners might reduce the last-mentioned objection to a minimum.

COMMERCIAL SANITATION IN THE MISSISSIPPI VALLEY

Steps are being taken by some of the sanitarians of the Mississippi Valley to secure concerted action by a number of transportation companies to enable the National Board of Health to continue its quarantine service after the time at which its lack of funds available for the purpose would otherwise render its discontinuance necessary. According to a recent statement by the secretary of the board, the funds in hand will suffice until the close of the current month, and an opinion has been obtained from the Treasury Department that the board can legitimately continue its quarantine and inspection service up to that time. It is for the purpose of carrying the work on after that date, as we understand it, that contributions are sought for from the corporations in question.

A REFORM IN THE ADMINISTRATION OF THE PARIS HOSPITALS.

HERETOFORE patients have not been received into the hospitals of Paris, unless conveyed thither by the police, having been injured in the streets, or unless admitted by order of the medical officers who make the regular morning visit. Consequently, those unfortunates who presented themselves in the afternoon were sent to the central office, whence they were obliged to make their way on foot to the particular hospital to which they might be assigned. Hereafter, however, as we learn from the "Union médicale," all applicants will be received provisionally into any hospital at which they present themselves, and, in case of their subsequent assignment to another, they will be conveyed to the latter in a vehicle. Moreover, the remnants of each day's meals are to be served to applicants the next morning, instead of being disposed of to a contractor, as heretofore.

THE CITY GOVERNMENT AND THE CONTAGIOUS DISEASES HOSPITAL.

WE lately chronicled a protest on the part of the Board of Aldermen against the establishment of the Board of Health's

hospital for contagious diseases at the foot of East Sixteenth Street. We are not aware that that protest constituted any legal impediment to the proposed action of the Health Department, and we are quite sure that with the thinking part of the community its moral effect was nil. Whatever importance may have seemed to attach to it in the minds of those of our citizens who mistake buncombe for an expression of solicitude on their behalf must now be swept away, in so far as persons at all open to enlightenment are concerned, by the action of the Mayor in communicating to the Board of Aldermen his disapproval of their resolution. "It requires no expert knowledge," says the Mayor, "to understand the importance of such a hospital as that which it is proposed to erect at the foot of East Sixteenth Street, but as to the proper location and construction of the building it seems prudent to rely upon the Board of Health."

THE PARIS NIGHT MEDICAL SERVICE.

ACCORDING to the "Union médicale," 1,865 visits were made during the first three months of the current year, against 1,978 during the corresponding quarter of last year—a falling-off of about one visit each night. Thirty-two per cent. of the patients were men, fifty-four per cent. were women, and fourteen per cent. were children under three years of age. Among the more urgent cases there were fifty-five of croup, nine of cholera, twenty-four of strangulated hernia, sixty-seven of abortion, two hundred and fifty-eight of parturition, sixty-nine of convulsions, one of hydrophobia, sixty-nine of hæmorrhage, thirty-nine of fracture or dislocation, fourteen of burns, fifteen of poisoning, six of coal-gas asphyxia, and two of suicide. In forty-seven instances the patient was dead when the physician arrived.

A TRAINING SCHOOL FOR THE BLOCKLEY HOSPITAL, PHILADELPHIA.

At a recent meeting of the Board of Guardians of the Poor, in Philadelphia, extracts were read from the minutes of the Hospital Committee, recommending "that the general plan now in use at the Charity and Bellevue Hospitals, New York, as relates to the employment and training of nurses, be introduced into the institution." It is said that the medical staff urged this measure, and agreed to recommend Dr. Seaman, who had had charge of the Charity Hospital Training School in New York, for appointment to a like position in the proposed school. The Board of Guardians felt obliged to defer action on the project, as they were not now authorized to spend money for such a purpose.

THE MEDICAL DIPLOMA INDUSTRY IN MASSACHUSETTS.

THE House bill for preventing the traffic in bogus medical diplomas in Massachusetts seems to be meeting with obstruction in the Senate. The House, however, insists on its bill, and a committee of conference has been appointed. It is to be hoped that the matter will end in the passage of an efficient bill by both houses, and that the Governor will not fear to offend his supporters by signing it.

THE ELECTRIC FRONTAL ILLUMINATOR.—With the aid of M. Trouvé, the electrician, M. Paul Hélot, a hospital surgeon of Rouen, has devised an illuminating apparatus, the *photophore électrique frontal*, consisting of an incandescent lamp contained in a metallic cylinder, with a reflector behind it and a bull's-eye condenser in front of it, the whole being attached to a head-band and worn on the forehead. It is said to be small and light, and to work for several hours at a time. The current is supplied by a Trouvé's supersaturated bichromate pile.

Proceedings of Societies.

NEW YORK SURGICAL SOCIETY.

A STATED meeting was held May 8, 1883, T. M. MARKOE, M.D., President, in the chair.

FRactURE OF THE PATELLA.—Dr. L. A. STIMSON presented a patient who had suffered from an ordinary transverse fracture of the patella. The result was very close union, but with recognizable mobility of the fragments upon each other. The treatment consisted in immobilization of the limb with a fenestrated plaster apparatus in the extended position, the fragments being held in contact with India-rubber tubing, one piece above and the other below the patella. The fracture occurred twelve weeks ago, and, when first examined, the fragments were separated from three fourths of an inch to an inch. An interesting feature in the case was the fact that the patient had suffered from fracture of the patella on the opposite limb fifteen years ago, which was treated with an iron horse-shoe arrangement, and apparently bony union had taken place.

Dr. Stimson presented a second patient with compound fracture of the patella, in whom the mobility of the joint was about the same as that in the first case two weeks ago. The details of the history of the case appear in his paper which follows.

Dr. Stimson then read a paper ON SOME COMPOUND ARTICULAR FRACTURES. [See p. 621.]

Dr. ALFRED C. POST said he remembered the time when compound fracture of the knee joint was regarded as *ipso facto* calling for amputation. He recalled a case in the New York Hospital, and under the care of Dr. Kearney Rogers—a laboring man who had his patella fractured by frozen earth falling upon the limb, and there was a free transverse wound opening into the knee joint. The surgeons decided that the limb should be amputated, but the patient decided that the operation should not be performed. The external wound was very free, so that drainage readily took place, and the patient recovered without any considerable amount of inflammation. This occurred about the year 1840, and, to the best of his recollection, was the earliest case which opened the eyes of the surgeons to the expediency of attempting to save the limb in cases of knee-joint fractures.

Dr. E. L. KEYES said he had just received a letter from one of his former students (Dr. Alexander), now in London, stating that he had recently followed Mr. Lister in the treatment of two cases of simple fracture of the olecranon by opening the joint, drawing the fragments together with wire, hammering the ends of the sutures down smoothly, and then closing the wound. The operations were performed under full antiseptic precautions, and all of the patients had done well; that is, neither suppurative nor inflammation had occurred. What the ultimate result would be with reference to mobility, of course had not been ascertained.

Dr. Keyes had treated one case, bearing on the subject, in Bellevue Hospital—that of a boy who had supuration of the knee joint with necrosis of the patella. The condition was due to a traumatic cause, the exact nature of which he did not recall, but the suppurative process invaded the joint. Dr. Keyes opened the joint freely upon both sides, passed a drainage-tube completely through the limb, and washed it out freely with an antiseptic solution. At about the same time supuration occurred above the patella, and he opened the abscess and finally removed the entire patella. In the dressing, simple cleanliness was observed and complete drainage secured, and the boy recovered, with a movable joint and a new patella.

Dr. H. B. SANDS recalled a number of cases in which recovery had taken place after compound fracture of joints. He remem-

bered one, a case of compound fracture of the patella, which he had treated in Bellevue Hospital. As in the case mentioned by Dr. Post, it was believed that the joint would suppurate, and it was thought that amputation was advisable; but, under simple dressings, the wound closed, supuration did not occur, and the man recovered with a perfectly normal joint.

He had seen a number of cases of fracture into the elbow joint which had recovered, some with, some without antiseptic dressing.

He had also excised the astragalus in two cases—one a compound dislocation with fracture, and the other a fracture in which the greater part of the bone was displaced, and pressed upon the soft parts, threatening mortification. In the last case an opening was made and the fragment of bone was removed. In the first case no antiseptic dressing whatever was employed. In the second case full antiseptic precautions were observed at first, but the physician under whose charge the case remained substituted a simple water dressing, and the patient did well. In both cases the patients recovered with a limited amount of motion at the ankle, as might be expected after such an injury.

Dr. Sands thought the point which Dr. Stimson made with regard to the concomitant injury of the soft parts in cases of fracture was a very important one. He believed that most surgeons would agree that often the least important lesion in a case of fracture is that of the bone, and that compound fractures often do badly because the soft parts are so severely injured that their vitality can not be maintained.

Whether American surgeons were not thoroughly well versed in antiseptic methods he was not prepared to say, but evidently the results obtained in this country were not so favorable as those which had been published in foreign journals.

Sometimes operation-wounds of joints pursue an unfavorable course in spite of every precaution. For example, in a case of old fracture of the patella treated at one of our hospitals by joining together the fragments with silver wire, the Listerian method was strictly carried out; nevertheless, supuration followed, and the patient lost her life. In another instance, in which a simple fracture of the patella was converted into a compound fracture, and the bones were wired together, the patient had a severe attack of inflammation of the joint, and was very ill for a long time, although she finally recovered, with a stiff joint. He should be disposed to treat a compound fracture of a joint by very careful washing with an antiseptic solution, by free drainage, and with the least amount of excision possible.

Dr. A. G. GERSTER was able to recall a few cases of fracture involving joints, one of which, perhaps, was worthy of mention. A grocer, while unloading a heavy cask, lost his balance, fell, striking upon one elbow, and the barrel rolled over the same arm. Dr. Caillé had charge of the case, and found an extensive compound fracture of the elbow joint, both condyles being involved, and a single split of the bone entering the joint, so that the whole fracture presented an appearance very much like that of the letter Y. The external condyle was completely detached. On the outside of the limb there was a large lacerated wound opening into the joint. The periosteum having been almost entirely torn from the external condyle, Dr. Gerster removed the bone, together with the eminence corresponding to the articulating surface of the radius. The spur-like, sharp projection of the diaphysis of the humerus was sawn off, and a counter-opening was made on the inner aspect of the joint. The wound was washed out well with a five-per-cent. solution of carbolic acid, drainage-tubes were inserted, and the wound in the soft parts was united by a sufficient number of sutures to give the joint a certain amount of support. Antiseptic dressings were applied, and the limb was placed upon a splint. When the patient came from under the influence of the ether he went

into a condition of violent mania, and thrashed about with the injured arm very severely. After he had been quieted by a hypodermic injection of morphia, the dressings were removed, and it was found that a large venous hemorrhage had taken place, which was controlled by pressure, and the dressings, with the splint, were reapplied. Despite the extensive injury originally done to the limb, and subsequently done by the violence of the patient, the case did very well. No fever followed, and Dr. Gerster attributed the result largely to the fact that it came under observation very early—before any infectious process had commenced in the wound. The final result was that perfectly good motion was established. A small fistula remained open about five months, and then closed, and mobility subsequently became perfect. Passive motion was begun about the third week. There may have been some new bone formation, but nothing like an external condyle developed. The radius was fixed in its normal position, and all of the motions of the limb were apparently complete.

Dr. Gerster related a second case—one of extensive injury of the ankle joint. The injury was caused by falling from a wagon, breaking the ankle, and the patient was brought into the hospital five hours afterward, where the wound was dressed without washing and simply by sealing it up. Within three days intense phlegmonous inflammation developed, and amputation was necessary in order to save the patient's life. Early and thoroughgoing antiseptic measures must decide the fate of the injured limb.

Dr. C. T. POORE referred to a case of compound fracture of the ankle joint which he saw when an interne in the old New York Hospital. The end of the tibia protruded, and was cut off. Suppuration of the joint occurred, but the man recovered, with good motion.

Dr. C. K. BRIDDON said that twenty-five years ago it was a disputed point as to whether it was proper or improper to resort to excision of protruding bones in compound fracture of the ankle joint.

Dr. Post said there was a case of malpractice on record for cutting off the protruding extremity of the bone under these circumstances, and, so far as he could recollect, it was decided in favor of the surgeon.

The PRESIDENT said that his own convictions were in favor of a certain plan of treatment well known to the society—namely, that by thorough drainage, and by the use of it he had secured very satisfactory results. The drainage-tube is retained in the wound until granulation has fairly begun. He had employed it in compound fracture of the elbow joint, but he did not remember to have used it in any case of similar injury to the knee joint. In the elbow joint he passed it through the capsule always behind the joint, and allowed it to remain from four to six days.

Dr. STIMSON asked if, in the third case which he reported, the President would have treated it by means of thorough drainage.

The PRESIDENT answered that he would not; that he would have in that instance sealed the wound with collodion.

EXCISION OF THE TONGUE AND FLOOR OF THE MOUTH; LIGATION OF BOTH LINGUAL ARTERIES.—Dr. BRIDDON presented specimens accompanied by the following history: David S., aged sixty-five, native of Ireland, single, laborer. Family history good; was not aware of any predisposition to cancer. No history of syphilis. Had been a smoker for thirty years. Three months ago he noticed something on the under surface of the tongue that impeded its movement, especially preventing protrusion. It gradually increased; was not exceedingly painful, but interfered with eating and talking. Had had no hemorrhages, but complained of pain in his left ear.

Admitted to Presbyterian Hospital April 27, 1888. Exam-

ination of the mouth revealed an irregularly shaped ulcer, involving the under surface of the tongue and the floor of the mouth as far forward as the internal surface of the anterior portion of the lower jaw. It involved principally the left side of the tongue, but, passing across the mesial line, it encroached on the right. Its edges were slightly everted, unequal, irregular, excavated, base indurated, motions of the organ impeded; he could not elevate its tip; ganglions not involved. Spontaneous lancinating pain, darting toward ear. Diagnosis, epithelioma. Removal advised.

Operation, May 2, 1888, 2.30 P. M., under the influence of ether. The superficial veins were very large, the facial, as it passed over the jaw, equaling in size the little finger; and, as the incisions had to be carried into close proximity with them, it was necessary to proceed with deliberation. On the right side the superficial structures were divided until the posterior belly of the digastric muscle and the hypoglossal nerve were exposed. The greater cornu of the hyoid bone was steadied with a uterine tenaculum; a curved needle, carrying a ligature, was then passed under and around it, and traction upon this brought the process nearer to the surface and steadied the hyoglossus muscles. An incision was then made through the muscles parallel with and below the nerve; the artery was exposed without any further difficulty, and was secured with a carbolized-silk ligature. On the left side the artery was tied within the digastric triangle. Considerable difficulty was experienced in separating the capsule of the submaxillary gland. It will be remembered that the disease was most extensive on this side of the mouth, and that might have had something to do with it. At all events, the gland was suspiciously indurated, but not so much so as to warrant its removal. It was not an easy matter to keep it out of the field of operation. The artery was found below the nerve, but it was more difficult to isolate than on the right side. It was also secured with a silk ligature.

Attention was then paid to the mouth. A scalpel was carried round the inside of the maxilla, close to the bone, but not quite anterior to the limits of the disease. The soft parts were then cleared from the surface of the genio-hyoid muscles by strong, blunt-pointed scissors. This dissection was carried beyond the limits of the disease, and then a transverse section completed the extirpation. A few small bleeding points were secured in the floor of the mouth, and all the soft parts covering the posterior surface of the front of the jaw were removed with the sharp spoon.

For three or four days there was considerable swelling below the left side of the jaw, but it sub-sided. Fœtor of the mouth diminished under the hourly use of a wash consisting of borax, glycerin, and tincture of benzoin, and now, six days after the operation, he was sitting up in bed, doing well.

FUNGUS ARTHRITIS; RESECTION OF THE ELBOW JOINT.—Dr. BRIDDON also presented fragments of bone removed from the elbow joint. Maurice W., aged forty, native of Ireland, married, longshoreman, said that his family history was good, and that he had always regarded himself as a healthy man. He fell on his left elbow three years ago, but continued to work for two years, complaining only occasionally of soreness in the joint. Eighteen months after the injury the joint began to grow stiff, and this condition increased until about eight months ago, when pain became more annoying, and it became red and swollen. Several incisions were made at that time, evacuating matter. The incisions contracted, and the discharge continued in diminishing quantity.

Admitted to Presbyterian Hospital April 23, 1888. General condition pretty good; left arm flexed to nearly a right angle. The elbow joint was occupied by a fusiform swelling that reached three inches above and four below the line of articulation. Move-

ments limited, but not accompanied by crepitus. Above the superficial swelling there could be detected a deeper seated swelling, evidently periosteal, and reaching to the middle of the humerus. There were several puckered cicatrices about the joint, and the partially healed remains of an incision recently made. Through several of these sinuses a probe appeared to traverse the joint, and at one point came in contact with carious bone.

Diagnosis, fungous arthritis. Resection advised. Operation was performed May 5th, under the influence of ether, by the ordinary method of procedure. The joint was found completely disorganized; cartilages destroyed; nearly everywhere the dense lamella of bone that underlies the cartilage was gone, and the cancellous structure exposed, its spaces filled with granulation tissue.

Dr. W. S. HALSTED suggested that the reason why Dr. Bridson experienced so much difficulty in securing the lingual artery upon one side was that his assistant, while attempting to draw the hypoglossal nerve out of the way with a hook, at the same time raised the lingual artery with it and the hyoglossus muscle. He thought this was the case, because as soon as the assistant relaxed his hold with the hook the artery was readily exposed. Dr. Halsted also offered the suggestion that, instead of dividing the muscle at right angles with the direction of the fibers, ligation would be facilitated considerably by simply separating the fasciculi to any extent which might be necessary without cutting.

Dr. BRIDSON remarked that he was particularly struck with the facility given to the operation by fixing the greater cornu of the hyoid bone with a thread so that it could be placed under the complete control of the assistant.

Dr. POST believed it to be a general surgical principle that wherever a loop of thread could be used instead of the forceps or hook to secure mere fixation, it was much more desirable than to employ the vulsellum or hook, or other means, as it was more secure.

Dr. STIMSON said it seemed to him, from the facility with which the tongue could be drawn out from the mouth, a fact mentioned by Dr. Bridson, that the hemorrhage might have been controlled very readily, even if it had been much more severe than it was.

Dr. BRIDSON said his impression was that Whitehead's operation would do away with the necessity of ligating the lingual artery at all in these operations.

The PRESIDENT remarked, concerning the second specimen presented by Dr. Bridson, that about three weeks ago he excised the elbow joint for caries, treated it with thorough drainage, and experienced no trouble whatever. No suppuration occurred outside of the joint, and the patient is far advanced toward recovery. The temperature was never elevated above 101° Fahr. He removed the drainage-tube at the end of six days.

MYXOMA-SARCOMA OF THE UTERUS.—Dr. F. LANGE presented a specimen consisting of a uterine tumor and the ovaries removed by supra-vaginal amputation, twenty-four days ago, from a woman forty-four years of age. Microscopical examination showed that the growth was myxo-sarcomatous, large spindle cells predominating. The entire mass, solid and fluid, weighed at least twenty-five pounds. The following history was given:

An otherwise healthy woman, had borne five children, the last being delivered fifteen years ago. Since that time she had been regular, but the menstrual flow had been somewhat abundant. About five or six years ago she noticed some increase in the size of her abdomen, but it gave her no trouble whatever, and she did not consult any one until a year and a half ago, when she consulted a woman who by some manipulation caused a watery discharge to take place from the vagina, and this was followed by a decided decrease in the size of the abdomen. After a short

period, however, the tumor again increased in size, and she then applied to her family physician, who told her that the growth of her abdomen was due to an increase in the size of the uterus, and that nothing could be done for her. Dr. Lange saw the patient first early in March of this year, at which time the distension of the abdomen was very great; the largest circumference was one hundred and twenty-two centimetres, due, apparently, in great part, to the presence of a solid tumor starting from the pelvis, and located chiefly in the right side of the abdomen. It extended upward to the ribs. The umbilicus was very much distended, and the fact that in the erect posture the umbilicus was protruding and was collapsed in the horizontal posture, together with the dullness prevailing in the lumbar region which cleared up when the patient assumed the lateral position, led him to the conclusion that there was a certain amount of fluid in the abdominal cavity. The tumor was movable in the lower part, but seemed to be attached at the upper part, where the patient complained of considerable pain. Before the development of this pain she had scarcely complained of any discomfort, except from the size of the tumor. There was a pronounced uterine murmur over the lower part of the abdomen. Afterward, examination showed the vaginal portion of the uterus very much elevated, so as to be scarcely touched with the finger; but movement given to the tumor from the outside was communicated to the vaginal portion. The probe entered the uterus to the depth of three inches without difficulty. The great distension of the abdomen left it in doubt whether cystic degeneration of the right ovary did not exist apart from the tumor of the uterus. An exploratory incision, however, was decided upon. In the apparently cystic portion of the growth a puncture was made, but fluid could not be removed, and subsequently it was proved that it was of a colloid character, which could not pass through the cannula. The elastic ligature was applied to the cervix extra-peritoneal, the growth was divided a short distance above the ligature, the stump was cauterized, powdered with iodoform, and then covered with peritonæum detached somewhat above. The external incision was about fifteen inches long. There were extensive and broad adhesions with the omentum and the transverse colon, but they were quite easily separated. Considerable difficulty was experienced when it was necessary to enter the small pelvis and reach the cervix, but this was overcome by tying the broad ligament with a double mass ligature and cutting across the mass with the thermocautery. There was also great difficulty in passing the chain écraseur about the cervix, which Dr. Lange did previous to the application of the elastic ligature. The tumor was separated at a good distance from the ligature preliminary to the final treatment of the stump. The blood-vessels within the chain écraseur and outside of the elastic ligature were tied for the most part separately; some of them, however, were embraced in the mass ligatures. The loss of blood was comparatively insignificant. The peritoneal cavity was carefully cleansed; large, flat sponges, dipped in a warm solution of salicylic acid, probably one to a thousand, covered the intestines during the entire operation, so that the hands did not come in contact with them. The wound was closed by at least seventy superficial and deep sutures. In order to form a thick abdominal wall in the middle line, the abdominal walls were brought together by eight lead-plate sutures introduced at a considerable distance from the cut edges. The peritonæum was sewed up by a continuous catgut suture. Only a very small covering was applied, consisting of a fine layer of gauze, powdered with iodoform and fixed in position with adhesive plaster. No spray was used, and the peritonæum was kept as dry as possible throughout the entire operation. From the first moment the patient was treated as though she was suffering from peritonitis; that is, as soon as

she rallied from the influence of ether and the shock and collapse had passed away, cold was applied locally, and opium with quinine was administered by the rectum. Thus far the progress of the case had been most satisfactory, and Dr. Lange believed that the patient was out of danger. Up to the sixth day she had a good pulse and temperature; but then, without apparent reason, the temperature rose to 104° Fahr. and 105° Fahr., and continued so for two days, while the pulse was from 70 to 80, and the general condition very good. The temperature then subsided, and had not since become elevated. He thought that the elevation of temperature was possibly due to the iodoform, which had been powdered somewhat freely into the abdominal cavity; at least he knew of no other reason to which it could be ascribed. The urine was examined for iodoform, and showed a trace of iodine reaction.

Dr. BRIDGON testified to the value of the flat sponges mentioned by Dr. Lange, which he had just employed in a case of double ovariectomy.

THE CONNECTICUT STATE MEDICAL SOCIETY.

THE Ninety-second Annual Convention was held at Hartford, May 22 and 23, 1883, the President, W. G. BROWNSON, M. D., in the chair.

Although fast approaching its centennial, it was never in a more vigorous condition. The migratory habit inherited from the State Legislature was not abandoned at the same time, so the next convention will meet at New Haven.

Wednesday—First Day.

THE PRESIDENT'S ADDRESS.—It is by law made the duty of the president to call attention to such subjects as he deems worthy of attention and action. In accordance with this, after a brief address of welcome, the president mentioned the following subjects as of importance: In the first place, the legal status of the society should be considered carefully, as, apparently by inadvertence, the charter of the society was lost in the revision of the charter of the Yale Medical Department, with which it was incorporated in a joint act. A general revision of the by-laws may be not inexpedient at the same time. He advised, should such action be taken, the following changes, namely: The addition of permanent fellows, composed of all ex-presidents, who should be called councilors, and have in charge all matters of discipline, select essayists, and perform such other duties as the society might direct. The secretary should be made a permanent officer and paid a salary, and perhaps the treasurer also. The number of delegates from the county societies should be increased in proportion to their increase in membership. The rapid increase of new remedies was deprecated, and the tendency to use them experimentally; a standing committee of four was advised to report annually such as had proved worthy of use. He announced with regret that, from press of other duties, the present secretary could no longer retain the position, and paid a glowing tribute to the value of his services to the society. The work of the State Board of Health was indorsed in the strongest terms, and the action of the Legislature in refusing to repeal the law concerning compulsory vaccination of school children commended; also its action concerning the coroner system—these both, in a measure, due to the influence exerted by this society. The tendency to exalt specialists at the expense of the general practitioner was deprecated, and the labors of the country doctor received their just meed of praise. In closing, he spoke of the code as an instrument that had nearly outlived its usefulness, and that should be supplanted by a higher law toward which we were advancing. The recommendations of the president were referred to proper committees.

AMENDMENTS PROPOSED.—Several other amendments were proposed and received for final action next year: That the member of the Nominating Committee and an alternate be designated by each county society. That alternates be chosen for each delegate. That all motions shall be legibly written, and all remarks written out either before or directly after they are made. That no voluntary paper shall be published unless read previously before some county society.

THE DUTIES OF THE CENSORS OF COUNTY SOCIETIES.—The amendment proposed last year relating to the duties of the censors of county societies was adopted upon a favorable report of the Committee on Unfinished Business.

THE LEGAL STATUS OF THE SOCIETY.—On motion of Dr. Chamberlain, the resolution concerning the Committee on the Legal Status of the Society was reconsidered, and the following, drawn up by Professor W. H. Carmalt, substituted, viz.: That a committee, consisting of one member from each county, to be selected by the fellows from the respective counties, be appointed to take into consideration the legal status of this society, with power to employ counsel, and to report at an especial meeting of this society to be called by the president. The motion passed, and the following were appointed: Dr. C. W. Chamberlain, Professor W. H. Carmalt, Drs. F. N. Braman, George F. Lewis, of Bridgeport, E. A. Hill, H. W. Buel, George W. Burke, A. R. Goodrich.

There was considerable discussion over this committee and its duties. The society, jointly with the college, confers degrees in medicine, and the latter is apparently somewhat restive under the relationship. It was expected that a resolution dissolving this connection would be introduced, as the way had been paved by an article in the daily papers, and as this could be done, according to the revision of 1879, by mutual consent without legislative interference. No such resolution, however, was offered.

THE PUBLICATION OF VOLUNTARY PAPERS.—The Committee on County Resolves reported upon a complaint against the Publication Committee that it was the duty of said committee to decide upon the publication of voluntary papers, but a difference of statements from their opinions was not a proper cause for rejection. The report, on motion of Dr. Chamberlain, was accepted.

HONORARY MEMBERS.—Dr. John S. Billings, Assistant Surgeon-General, United States Army, was elected an honorary member, and Dr. James E. Reeves, of West Virginia, and Professor T. A. Emmet, of New York, were proposed by the committee for action next year.

OFFICERS FOR THE ENSUING YEAR.—The Nominating Committee reported the following list of officers, which was duly elected: President, Dr. E. B. Nye, Middletown; Vice-President, Dr. B. N. Comings, New Britain; Treasurer, Dr. E. B. Swasey, New Britain; Secretary, Dr. S. B. St. John, Hartford; Committee on Matters of Professional Interest, Drs. W. C. Wile, J. H. Grannis, and E. C. Kinney; Examining Committee, Drs. George F. Lewis (Bridgeport) and M. Storrs; To Nominate Professors to Yale Medical School, Drs. J. G. Stanton and J. B. Kent; To Nominate Physicians to the Insane Retreat, Drs. R. Hubbard and R. W. Matthewson; Committee on Publication, Dr. I. W. Lyon; Committee on Arrangements, Drs. J. P. C. Foster, C. P. Lindsley, and S. G. Chapman; Dissertations, Dr. N. E. Worden; Alternate, Dr. W. H. Holmes. Delegates to other medical conventions were chosen as follows: American Medical Association, Drs. G. W. Avery, S. G. Hubbard, W. C. Burke, Ellis Paddock, T. M. Hills, W. J. Beach, S. G. Risley, W. B. Hallock, F. L. Dibble, and F. S. Young; Maine convention, Drs. C. J. Fox and P. H. Ingalls; New Hampshire convention, G. W. Russell and M. C. Hazen; Vermont convention, Drs. Seth Hills and

Frank Coates, Jr.; Massachusetts convention, Drs. F. E. Beckwith and J. G. Stanton; Rhode Island convention, Drs. C. M. Carleton and R. M. Griswold; New Jersey convention, Drs. H. P. Geib and J. G. Gregory.

DELEGATES TO THE NEW YORK STATE SOCIETY.—When the delegates to the New York Medical Society were reached it was moved by Dr. Porter that the nominations be laid upon the table, stating that the attitude of the society toward the American Medical Association rendered such action advisable upon our part, and that similar action had been taken by other societies. The motion was then passed.

TREASURER'S REPORT.—Dr. Swasey then presented his report as treasurer, showing the largest balance in the treasury for many years, if not, indeed, the largest, in round numbers, \$640, an increase of \$200 over that of last year. The expenses had been about \$80 less, the receipts about \$40 more. The recent gain in the treasury was due to the collection of arrearages in Fairfield County by Dr. Wilson, and New Haven County by Dr. Holmes, while there were about \$100 due still on last year's tax, mostly in Fairfield County. There were no arrears extending beyond what was doubtless all collectable. Three counties report no indebtedness, and the amounts in three others are slight, so the condition is fully equal to last year.

THE SALE OF PATENT MEDICINES.—Upon motion of Dr. Chamberlain, it was voted that this society memorialize the Legislature for a law requiring that no patent or proprietary medicine be allowed to be sold in this State unless the formula is plainly printed on the label, with a heavy fine if analysis should show any essential difference from the formula.

PUBLICATION OF THE PROCEEDINGS.—The usual tax of two dollars was assessed, and seven hundred copies of the proceedings ordered published.

REPORT OF THE BUSINESS COMMITTEE.—The Committee on Business, in addition to several amendments before considered, reported favorably upon the plan proposed by the Massachusetts Medical Society for a medical register of the New England States. The committee also reported a set of resolutions indorsing the Army Medical Museum and Library of the Surgeon-General's office, deprecating their separation, and requesting Congress to provide suitable accommodations in a fire-proof building; also a suitable annual appropriation—not less than \$15,000. The Index Catalogue was declared to be of inestimable value to the whole medical profession, and Congress petitioned to make the appropriation needed for its continuance. A copy of these resolutions was ordered sent to each member of Congress from this State, and members of the society requested to use their individual influence to secure these objects.

The report of the committee was accepted unanimously.

REPORT OF THE COMMITTEE ON THE CODE.—A committee on the code appointed last year reported in substance that if any changes were to be made they should originate in the American Medical Association, where it originated. The report was accepted, and the committee discharged.

A RECEPTION TO THE SOCIETY.—There was a very pleasant reception given at the United States Hotel, Wednesday evening, to the delegates by the Hartford Medical Society.

Thursday—Second Day.

REPORT OF THE SECRETARY.—The second day's session opened promptly at half past the report of the secretary, who stated that the year had been marked by the same uninterrupted prosperity that had been characteristic of the recent history of the society. There was, it was true, a heavy loss by death both in numbers and in the character of the decedents, many of whom were among the oldest and most active members of the society, and, with scarcely an exception, all having an unspotted name

and fame. There were also those among them whose reputations extended beyond the borders of their own States. Dr. George B. Hanley was widely known as a humanitarian, while the monuments to his name in the Hartford Hospital and Old People's Home would testify of his zeal and devotion to coming generations. Nor was the fame of Dr. E. P. Bennett as a surgeon confined to his native country. Others will long be missed in these meetings. Although there have been fourteen deaths, the new members number thirty-one, so that, after all losses are deducted, there remains a net gain of ten, making our membership four hundred and sixty. In retiring from an office held for the past eight years, the secretary desired to express his sincere thanks for the society's cordial co-operation in his earnest endeavors to serve faithfully the interests of the society, which alone allowed him to transfer his duties with the society in so flourishing a condition, both as to membership and as to financial matters. During this term of eight years there have been eighty-six deaths, and the usual losses by removal, etc., yet the society has gained over a hundred members, having an average of thirty new members each year; and there are four hundred dollars more in the treasury than there were eight years since, and no back taxes due except on the current year—a state of affairs unknown in the financial history of the society hitherto, and found elsewhere in few, if any. After a résumé of the duties, trials, and rewards of the office, he renewed his thanks for the kind support received and the expressions of regret at his retiring from office.

Professor WHITE moved that the thanks of the society be tendered to Dr. Chamberlain for his long, faithful, and arduous services for eight years as secretary.

Dr. WILE, after heartily indorsing the resolution and referring to the promptness of the publication of the proceedings and the favorable reviews they received, moved as a substitute that a committee of three be appointed by the chair to draft and have engrossed suitable resolutions, to be presented to the retiring secretary as a slight expression of appreciation of his services.

The motion was passed, and Drs. W. C. Wile, M. C. Hazen, and George L. Porter were appointed.

THE ANNUAL ADDRESS.—The president-elect having been called to the chair, the retiring president presented the annual address this year, in a poetical form, on the Country Doctor—a graphic pen picture of the life of the rural practitioner, which elicited the frequent applause of the listeners. The poem must be read to be appreciated. A brief extract may serve as a sample of the method of treating the subject; it is the description of a consultation:

"An only child, within whose tender life
Center the fondest hopes of husband, wife,
And many friends, seems on the eve of death,
Convulsed with pain; with fluid, red of breath,
Clenched hands, eyes sunken, nostrils stretching wide,
He scarce can count the pulse's hasty stride—
He looks at his thermometer amazed,
Its column to a frightful degree raised;
Ah, you and I have felt his agonies here,
And wished some able compeer were near
To aid in such extremity, or bear
Of such responsibility a share.
No time to lose, he summons to his aid
His nearest rival; time is quickly made,
And, Jehovah, with flashing speed to drive,
And at the moment spoken arrives.
In manner business, prompt in act and stride,
He greets his brother with the kindest stride.
With new-found friends shakes hands with relish keen
Happy to see them, happier to be seen

His conversation he directs to these,
 With studied effort to attract and please;
 Tells of an anxious case he had last night,
 Which by his skill is coming out all right;
 Details his treatment in a learned way,
 Bold and heroic as we sometimes say;
 Consults his watch, and softly names the time
 When he must see a case with Doctor Prime;
 A city lady, wealthy and refined,
 Attractive both in person and in mind.
 His fine impressions made, he condescends
 To interview the doctor and the friends;
 And, ere he sees the case, states his belief
 That he can soon suggest a prompt relief.
 He quickly scans the case, and feigns to see
 At once the lesion and the remedy;
 Tells of a dozen cases he has had
 Within a year with symptoms quite as bad.
 And thus the farce of consultation ends;
 What further he discloses to the friends
 We ne'er shall know; but somehow it transpires,
 He gets the case—his brother soon retires.

DELEGATES FROM OTHER STATE SOCIETIES.—The following delegates were then introduced to the convention, who presented briefly the congratulations and kind wishes of their respective societies, viz.: Dr. G. J. Townsend, from Massachusetts; Drs. A. G. Browning and Charles O'Leary from Rhode Island Dr. St. John read a telegram from Dr. D. C. English, of New Jersey, regretting his inability to be present. Dr. T. D. Crothers presented credentials from the "American Association for the Care of Inebriates." Drs. M. H. Henry and G. Sawyer, from New York, were invited to be the guests of the society.

Dr. HENRY presented, by request of the society, a paper on the treatment of varicocele, in which he described the operation that bears his name, and exhibited the clamp of his invention.

Dr. CHAMBERLAIN related briefly two cases where this operation had been satisfactorily performed by Dr. George C. Jarvis, of this city.

MICRO-SPECTROSCOPY.—Professor M. C. WHITE, of the Medical Department of Yale, presented a descriptive paper on this subject, exhibiting an instrument of his invention, and illustrating its construction. It consists in the introduction of a Jackson micrometer in the micro-spectroscope in the eye-piece, and a non-magnifying telescope in which the eye-piece and field-piece are of the same power.

EXTIRPATION OF THE ENTIRE UTERUS.—Dr. W. C. WILE reported a case where the patient lived five days. The operation was undertaken as a forlorn hope.

A CASE OF RESECTION OF THE HIP JOINT IN A MAN OF FORTY-FIVE was also reported by Dr. Wile. The patient had *morbus coxarius* as a boy, which had healed spontaneously, with some shortening. He had been treated for three months for spinal myelitis by the best specialists of New York city. On his return Dr. Wile found symptoms of iliac abscess, which the patient would not allow him to open. It should be stated that the patient was paraplegic, and had no sensation in the paralyzed parts of the body. When the abscess opened, a large quantity of sanious pus was discharged. The pain that followed was so severe that an operation was allowed. The head of the femur was absorbed, and there was a burrowing abscess extending to the lower angle of the scapula. Several inches of the femur were removed, and the patient made a good recovery. The paraplegia disappeared. He also exhibited a specimen of a tibia recently excised from the leg of a boy suffering from osteitis produced by a fall upon a sharp edge of a board a year previous.

SUCCESSFUL REMOVAL OF THE ENTIRE UTERUS.—Dr. W. C. BURKE, Jr., related a case where he had removed the entire uterus successfully for cancer, and exhibited an instrument of his contrivance for placing the stitches high up, without traction, upon the broad ligament, which he considered as one of the great causes of bad results in this operation.

EXTRA-UTERINE PREGNANCY.—Dr. G. L. PORTER reported a case where the child's head protruded, the fimbriated extremity forming a collar around its neck. The woman died of asthenia.

VESICAL CALCULI.—Professor WHITE reported a post-mortem in which twenty-two calculi were removed from the bladder. They were mostly in a cul-de-sac behind a greatly enlarged prostate. *Outside the bladder, in the cellular tissue, there were fifteen concretions, from the size of a pin-head to that of a pea.* One, carefully examined, proved to be made up of phosphate and carbonate of lime.

POINTS IN ORAL SURGERY.—Dr. GEORGE S. PARMELEE then read an essay on this subject, of interest to the general practitioner, in which the relations of imperfect and diseased teeth to dyspepsia and various other conditions were described, and other nervous diseases besides neuralgia, which alone is generally recognized as thus caused. The modern methods of treatment of the teeth were also graphically described.

THE TREATMENT OF PLEURISY BY ASPIRATION.—Dr. W. H. HOLMES then presented an admirable *résumé* of the treatment of pleurisy by aspiration with illustrative cases.

COMPLICATIONS IN LABOR.—Dr. F. N. BRAMAN then presented a very able and interesting essay on this subject, which showed considerable original research. He discussed hour-glass contraction, external version, the use of the fillet around the shoulders, and described its use in fixing and giving entire control of the body of the child in rotation by placing the fillet around the body of the child.

The paper was discussed by Professor BECKWITH, who stated that the use of the fillet around the shoulders was well known, and in general use, but its use around the body was original with Dr. Braman; but he considered it of no advantage over the use around the shoulders, theoretically, as all the force the child's body could stand could be thus exerted.

Dr. BRAMAN stated that he did not use it to obtain more force in traction, but as an aid in rotation, gaining by its use complete control of the body of the child, which the fillet around the shoulder would not always, if ever, give.

THE TREATMENT OF INTERMITTENT FEVER.—Dr. A. BEARDSLEY then presented a paper on this subject, and narrated a course of treatment which had been successful in his hands when quinine had failed. It was, in brief, an alterative purgative, aloes, blue mass, and capsicum, in equal parts, to be used freely, sometimes substituting calomel for the blue mass, an aromatic tonic combined sometimes with an alkali, and boneset tea drank freely several times a day.

The doctor wrote from a long and wide experience, and claimed success where quinine, pushed even to twenty grains two or even three times a day, had failed. The treatment seemed to be original, as no one who was present had followed it. The benefit of a mercurial purgative in commencing treatment was quite generally conceded.

After several minor matters of business were transacted, the society adjourned, for the annual dinner at the United States Hotel.

The session was unusually well attended, and the convention, on the whole, was one of the most satisfactory yet held. The society is to be congratulated upon its prosperity.

AMERICAN MEDICAL ASSOCIATION.

[BY TELEGRAPH TO THE NEW YORK MEDICAL JOURNAL.]

The thirty-fourth annual meeting was held at Cleveland, O., on Tuesday, Wednesday, Thursday, and Friday, June 5, 6, 7, and 8, 1883.

Tuesday—First Day.

Dr. X. C. SCOTT, Chairman of the Committee of Arrangements, introduced the Right Rev. Richard Gilmour, Bishop of Cleveland, who invoked the Divine blessing on the meeting of the association.

Dr. Scott then introduced John A. Atlee, M. D., of Pennsylvania, president of the association.

GENERAL MEYER'S ADDRESS OF WELCOME.—Amid the welcoming applause the President stepped forward, bowed his thanks, and introduced General Edward C. Meyer, the eloquent soldier, who made a deep impression upon his audience and was frequently interrupted with applause. General Meyer closed by giving the gentlemen a most cordial welcome to Cleveland, and wishing them God-speed in their noble work.

At the conclusion of General Meyer's address of welcome, President Atlee invited the vice-presidents and ex-presidents to the stage, after which Dr. Scott announced the programme for the entire session, and stated the places of meeting assigned to the different sections of the association. All protests relating to the erasure from the roll of the names of those who had not signed the code of ethics were referred to the Judicial Council.

THE PRESIDENT'S ADDRESS.—Gentlemen of the American Medical Association: Permit me to express my feelings of gratitude for the unexpected honor conferred upon me at the last meeting of the association, and to cherish the hope that in fulfilling the duties of this responsible position I may be sustained by your cordial co-operation. We meet here to engage earnestly in furthering the interests and objects of the medical profession. We have come together from all parts of our broad country charged with these great responsibilities. It is fitting to express here deep regret at the absence from our councils of delegates from the Medical Society of the State of New York. Let us hope that this absence may be only temporary, and that at the next meeting every State may be represented. [Applause.]

As specialties are so much in favor at the present time, I have thought it well, though far from favoring them on ordinary occasions, to bring prominently forward in my address today my own rare specialty, namely: that of being a graduate of sixty-three years' standing. Instead, therefore, of calling your attention to the more scientific subjects that are generally considered upon such an occasion as this, it has occurred to me that some reminiscences of my early medical life might not be wholly unacceptable or devoid of interest and instruction. [The President here indulged in a lengthy but pleasant recital of his early career, after which he continued, with the garrulity and, as he expressed it, the privilege, of an oldest brother, to present some reminiscences of his college life.]

Before I close this address, let me briefly call your attention to some other subjects, which in my opinion are pressing and important. Let me impress upon the mind of every member of the profession the necessity of strict and undivided attention to the duties of this high calling. Let no outside influence operate to interfere with those duties. When you undertake the care of a patient, your whole duty belongs to him; the intermission of a single visit, occupying time which on your part may have been devoted to pleasure, may sacrifice the life of your patient. Above all things, ever strive to maintain the honor and dignity of the profession. Let no selfish or ordinary consideration deter you from observing the laws laid down in our noble code of

medical ethics, cultivate friendly relations with your local medical brethren, more particularly the younger, and regulate your intercourse with all men in such a way that no stain shall be cast upon the honor of the profession, which is in your keeping.

In my day, previous to the establishment of medical societies throughout the country, before the organization of the American Medical Association and the general adoption of the code of ethics, I saw many disastrous effects from the want of brotherly consideration and kindness. The medical men of that day were often in difficulties: patients would be taken from one physician to another without ceremony, and so great was the jealousy existing between them that for more than twenty years after my graduation it was impossible to form a medical society in my native city and county, because there were so many aspirants for the honors.

Here let me speak of some of the difficulties I had to encounter in my early professional life. Instead of being taken by the hand by the older physicians, every obstacle was thrown in my path. Consultations were refused, and the treatment of my patients was unfavorably criticised. By the establishment of medical societies and the adoption of the code of ethics a wonderful change has been effected; we now feel it our duty to sustain our younger brethren, to treat them with courtesy, guard them from error, and encourage them in all their good works. Had the adoption of the code of ethics had no other result than this, it would have been an invaluable blessing to the profession. But it has accomplished more. It has put the seal of condemnation upon all "isms," and developed an *esprit de corps* that has enlarged the boundaries of our sphere, and greatly increased the usefulness and social standing of the profession. [Applause.]

Now, gentlemen, before concluding let me state that, being aware that reports and papers upon many important topics connected with the different departments of medicine will be presented by the chairmen of the sections and by individual members, I have not entered upon the discussion of any subject, either medical or surgical. Our meetings are for the purpose of promoting social intercourse as well as the advancement of medical science, but we should devote sufficient time to the discussion of the various subjects presented to us, and all of them may be greatly interfered with by social entertainments. One word more and I have done—and I say it chiefly as a word of encouragement to the younger among you. At the close of a long life devoted unreservedly to the practice of medicine, I will say that, notwithstanding its uncertainties, its anxieties, its fatigues, its bitter disappointments, I am completely satisfied that in no other career can a man more fully accomplish his whole duty to God and to his fellow-men, so that, when his life here is ended, it can be truly said of him, as—be it spoken with all reverence—was said of Him whom we should all imitate, *pertransit beneficentis*.

Trusting that our proceedings may be both harmonious and profitable to us all, and thanking you again for the honor you have conferred upon me, I sincerely hope that the recollections which we shall carry home with us will be most agreeable and lasting. [Continued applause.]

The PRESIDENT here announced that any member present who had papers to present would please hand them in and they would be referred to the different sections.

On motion of Dr. HEDGE, of Pennsylvania, the members of the Ohio State Medical Society were invited to seats on the floor.

Dr. SCOTT here gave a list of the railroads that gave reduced rates.

On motion of Dr. KILLEN, of Arkansas, an expression of thanks was tendered to President Atlee for his address, and the address was referred to the Committee on Publication.

Dr. J. S. BILLINGS presented a communication from the secretary of the British Medical Association, which was referred, on motion of Dr. Billings, to the Committee on Atmospheric Conditions and their Relations to the Prevalence of Diseases.

Dr. H. D. DIDAMA, of Syracuse, N. Y., presented a paper from Dr. J. H. Tyndale, of New York, in which Congress, the Secretary of War, and the Signal Service Department were petitioned to appoint a committee of five professional gentlemen to establish climate observations at the various health resorts for the benefit of pulmonary invalids. On motion of Dr. Didama, the petition was laid on the table, to be taken up for discussion in the Wednesday morning session.

On motion of Dr. ROBERTS, the secretary was instructed to call the roll. Some slight objections were made to the reading, but they were finally waived. After roll-call, the various State delegations met and selected representatives to serve on the Nominating Committee for officers of the association for the coming year.

COMMITTEE ON NOMINATIONS.—The following delegates were elected as a Nominating Committee; Dr. H. D. Didama, of New York; Dr. Alexander Harris, of Virginia; Dr. E. H. Gregory, of Missouri; Dr. Eugene Foster, of Georgia; Dr. D. G. Roberts, of Tennessee; Dr. R. A. Watson, of New Jersey; Dr. C. Johnson, of Wisconsin; Dr. W. C. Robertson, of Iowa; Dr. F. K. Owen, of Michigan; Dr. T. M. Hills, of Connecticut; Dr. William Beach, of Ohio; Dr. A. J. Fuller, of Minnesota; Dr. C. A. Savory, of Massachusetts; and Dr. L. S. McMurtrie, of Kentucky.

The meeting then adjourned until Wednesday at 9.30 A. M.

(To be continued.)

Letters to the Editor.

THE RECENT ACTION OF THE ACADEMY OF MEDICINE.

NEW YORK, June 2, 1883.

To the Editor of the *New York Medical Journal*:

SIR: In the "Ephemeris" for May, 1883, Dr. Squibb, in a most excellent article on the recent action in the Academy, advances certain ideas which must strike every one as singularly wise and timely.

In defending the propriety of this action, he shows that it is inconceivable that any candidate could be acting in good faith who should say: "I will yield loyal submission to the by-laws of the Academy while they continue in force, notwithstanding I believe them to be in some points unwise and injurious to the best interests of the profession, and notwithstanding I intend to use my influence in all legitimate and proper ways to bring about their amendment." Such a position being utterly absurd, the idea that there is any injustice or indelicacy in assuming in advance that he would break his promise at the first opportunity is only on a par with the cant about "more refined ethics," etc., of which we have had a surfeit. Such notions are put forward by impracticable sentimentalists who are incapable of the vigorous and wholesome hatred of medical heretics which should be handed down to coming generations as the only bulwark of professional dignity.

Another very valuable point made by Dr. Squibb is this: that sign, ing the constitution and by-laws of a society carries with it a pledge to support them unchanged and unamended, and that the only way of escape from this obligation is to resign. The great value of this position from a conservative point of view is at once apparent. Nothing could be more admirably calculated to insure stability and to prevent dangerous innovations. If the Academy will have the wisdom to adopt this principle into its organic law, it will prove an anchor to keep it from being carried along in the current of new ideas which threatens to sweep away so many of our time-honored and revered traditions.

Dr. Squibb deserves and will receive for this admirable article the hearty thanks of all those in the profession who do not allow fanciful ideas of "progress" to obscure their sense of what is due to themselves and to the ancient guild to which they belong.

BOURBON.

Miscellany.

TWO QUACK DOCTORS.—"On the 14th of March last a certificate was issued by the State Board of Health entitling one Julius Nothhelfer, of 701 Pine Street, St. Louis, to practice medicine and surgery in Illinois. The application for this certificate was based upon an affidavit that Nothhelfer was a graduate of the St. Louis Medical College, and this was corroborated by a letter from a member of the faculty of that institution, in which he says: 'I can sincerely indorse Dr. Julius Nothhelfer, a graduate of the St. Louis Medical College at the session of 1879-'80, as to his moral and professional character and standing.' In his first letter, March 7th, Nothhelfer states that he intends 'to practice in a country town in Illinois.'

"On the 24th of the same month a similar certificate was issued to one Joseph Fitzgerald, also of 701 Pine Street, St. Louis, and this was granted upon an affidavit that Fitzgerald graduated from the Royal College of Surgeons, Ireland, in 1871. The affidavit was accompanied by a number of letters 'bearing testimony to the capabilities of Dr. Fitzgerald as a medical man . . . eminently suited to take charge of any institution requiring a courteous and skillful medical officer.' These were all written in Dublin, none later than 1874; and, as this was not deemed recent enough by the secretary, a rather cautiously worded letter was forwarded by Fitzgerald from a prominent St. Louis physician, its reticence being plausibly explained by Fitzgerald on the ground of the latter being a stranger in that city. Fitzgerald requested that his certificate be sent to Belleville, St. Clair County, where he proposed to practice.

"Last week the attention of Dr. Rauch, the secretary of the State Board, was attracted by a large three-column, four-paged circular, headed 'The Great Surgeons, Drs. Nothhelfer and Fitzgerald, late of London, Eng., graduates of King and Queen's College, will be at the Commercial Hotel, 100 to 104 Lake Street, Chicago, for one month. Terms for treatment, cash. Charges from \$10 to \$500, owing to the requirements of the case.'

"In this circular they not only promise to cure every imaginable disease, but offer \$500 reward for an incurable case. Interentially, it is the bulletin of the 'St. Louis Medical and Surgical Institute,' an establishment which, it is safe to say, has no tangible existence, but which, in this sheet at least, is equipped with the 'most perfect surgical instruments and appliances, furnishes the most approved methods of treatment, and treats successfully the great majority of those diseases and deformities considered and given up as incurable.' Everything is done by 'new methods of treatment, new and recently invented instruments, and new and recently discovered remedies.' Some of the passages are unique even in quack literature. For example, the section on 'diseases of the sexual organism.' This is headed 'Manhood and Womanhood. The worst cases completely restored to health and the enjoyment of life,' and closes, after the usual disgusting recital, as follows: 'We would invite the attention of those of either sex afflicted in this manner to our new and successful method of treating this class of diseases,' and 'guarantee a positive and permanent cure' in every case of 'Manhood and Womanhood.' Of course, correspondence is solicited after the usual method and for the usual purposes of the infamous fraternity: consultations are free, and every imaginable device is employed to entrap the victim. What is meant by 'consultation free' was tested yesterday, when they offered to visit and prescribe for an imaginary patient gratis, but would charge \$10 for the medicines.

"The case is such a flagrant one, and comes so clearly within the authority of the Board, unhampered by the 10-year exemption clause, which shields the Drs. James Kean, Clark, and others, that the secretary laid the facts at once before the individual members and received

their prompt authorization to revoke the certificate. After to-day, therefore, any professional act performed by 'the great surgeons, Drs. Nothelfer and Fitzgerald,' in the State of Illinois, will subject them to fine and imprisonment in the county jail."

The foregoing was published in the Chicago and St. Louis morning papers of May 24. Before noon of that day the street distributors of the circular had been arrested, and within twenty-four hours Nothelfer and Fitzgerald had fled. It is understood they went to Milwaukee.

THE PATHOLOGY OF NOMA.—"The possibility of the dependence of noma on the presence of micro-organisms," says the "Lancet," "is certainly not small. More than the usual number of difficulties would, however, appear to surround the investigation of this severe disease. Inducing gangrene at an early stage of its procedure, the disease tends to become mixed up with a septicæmia or sapræmia, the outcome of the putractive changes in the necrosed tissues. So that organisms found at the site of the local disease or in the circulatory fluids of the body, unless they assume morphological appearances of an unusual kind—apparently a very unlikely occurrence—might either be specifically related to the disease or be nothing more than septic bacteria. Hence we are not disposed to place much reliance on some recent investigations made by Batta Segale. Micrococci and bacilli were demonstrated in the detritus obtained from the gangrenous sore; moving rods and vesicular corpuscles of a bluish tint were detected in the liquor sanguinis of some blood obtained from the tip of the finger. The bacteria were cultivated outside the body. Inoculations were performed on male and female guinea-pigs; in the former some blood from a diseased child was injected into the external jugular vein; the blood of the animal soon after was found to contain bacilli. Nevertheless, recovery ensued. The female guinea-pig was inoculated in the lower lip with the contents of a Pravaz syringe filled with fluid in which the bacteria had been cultivated. The following day gangrene appeared at the site of vaccination. Examination of the detritus of the affected part detected numerous micrococci, vibrios, and a few bacilli, all endowed with an oscillatory motion. The blood was normal till the eighth day, when some rod shapes were observed. Notwithstanding, the animal recovered. We need hardly point out the sources of fallacy in the observations sketched above. There would be but little objection to the notion that purely septic fluids and bacteria would be quite competent to explain the whole of the phenomena observed. The vesicular corpuscles mentioned possibly owed their blue tint to the non-use of an achromatic condensing lens. Neither the kind nor the powers of the microscope employed are named, nor is anything said of the sort of fluid used for cultivation. Although much may be learned from the employment of the simple forms and only moderate powers of ordinary microscopes, there can be no doubt that a condensing lens of achromatic properties, with a homogeneous medium, obtained either by oil or water immersion lenses, has now become essential for really efficient high pathological work."

HAMMER CRAMP.—"At a recent meeting of the Medical Section of the Academy of Medicine in Ireland, a report of which we find in the "British Medical Journal," Dr. R. McDonnell showed a young man, aged twenty-two, whose right arm was subject to muscular spasms. He was a nailer, and had been, since he was eleven years old, more or less hard at work at this occupation. The spasmodic jerking of the muscles, which interfered with his occupation, began about seventeen months ago, and, after the first three months, became so violent that he had to give up work altogether. The case was one of functional spasm unaccompanied by pain. This was an affection very similar to writer's or scrivener's cramp, although all the muscles supplied by the brachial plexus seemed to be affected, and these around the shoulder joint, especially the great pectoral, seemed to be most so. The treatment consisted in regular, orderly, rhythmical movements of the limbs as was successful in a very similar case reported by Dr. G. V. Poore in the "Practitioner" for September, 1872.

BINAURAL STETHOSCOPES.—"That there is 'nothing new under the sun' receives a fresh illustration in an old binaural stethoscope to be seen at Messrs. Caswell, Hazard & Co.'s, in the possession of Mr. Ford, the instrument-maker, who thinks that it was made in France certainly

before the present century. In great part it is made of silver, the ornamentation of which indicates its age. It is almost the exact counterpart of the instrument devised by the late Dr. Cammann, the flexible tubes being made of spiral wire covered with velvet. It lacks the ear knobs. The degree of approximation of the ear tubes is maintained by means of a set-screw.

PLEURO-PNEUMONIA AMONG CATTLE IN THE DISTRICT OF COLUMBIA.—"Contagious pleuro-pneumonia having been reported to have broken out in Washington, the Department of Agriculture and the District Board of Health are co-operating in an investigation. Dr. Townshend, of the Board of Health, has made an autopsy that leads him to the conclusion that the cow examined was affected with the disease in question; but Commissioner Loring and Dr. Salmon, of the Department, are not convinced. At all events, we are assured that the disease is not widespread as yet.

THE ILLINOIS STATE MEDICAL SOCIETY AND THE STATE BOARD OF HEALTH.—"At the recent annual meeting of the Illinois State Medical Society, the following preamble and resolutions were unanimously adopted:

Whereas, The Illinois State Medical Society was deeply interested and took an active part in promoting the formation of the State Board of Health, and the result of its work since its organization fully justifies the expectations of its originators in protecting the public from professional ignorance and imposition, from epidemic diseases and various other causes prejudicial to life, and in the promotion of a higher standard of medical education, thereby placing Illinois in the front rank among her sister States in this respect; and

Whereas, This result is largely due to the personal sacrifices of the members of the board, the appropriations by the State heretofore having been insufficient to carry out the duties imposed upon it by the law; therefore, be it

Resolved, That, in the opinion of this society, it is the duty of the Legislature of this State to make such appropriations as will enable the board to carry out the important duties assigned it by the act creating the State Board of Health and the act to regulate the practice of medicine.

Resolved, That a copy of this preamble and resolution be sent the members of the Legislature now in session.

THE FRENCH ACADEMY OF SCIENCES.—"At an election recently held to fill the vacancy in the Section of Medicine and Surgery caused by the death of M. Sédillot, on the first ballot the vote stood: whole number, 57; necessary to a choice, 29. M. Richet had 22, M. Brown-Séquard 18, M. Jules Guérin 14, M. Sappey 2, M. Charcot 1. On the second ballot the whole number was 58; necessary to a choice 30; M. Richet had 32, M. Brown-Séquard 23, M. Jules Guérin 3. M. Richet was, therefore, declared elected, subject to the approval of the President of the Republic.

THE COLLEGE OF PHYSICIANS AND SURGEONS OF CHICAGO.—"Professor William E. Quine has resigned his chair in the Chicago Medical College, and has accepted the chair of Practice of Medicine in the College of Physicians and Surgeons of Chicago.

THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.—"Dr. William J. Morton, after a year's successful teaching, has resigned the Associate Professorship of Diseases of the Mind and Nervous System in the New York Post-Graduate Medical School. Dr. Charles L. Dana, Professor of Physiology in the Woman's Medical College, has been elected to share the chair of Mental and Nervous Diseases with Dr. William A. Hammond.

THE MEDICAL SOCIETY OF LOUISVILLE.—"This is the name of a new medical society in Louisville, Ky., of which Dr. Preston B. Scott has been elected president, Dr. L. P. Yandell first vice-president, Dr. Coleman Rogers second vice-president, Dr. W. B. Dancy secretary, and Dr. D. W. Yandell, Dr. Turner Anderson, Dr. H. K. Pusey, Dr. William Bailey, and Dr. J. A. Oetzelony a judicial council.

THE NEW YORK DERMATOLOGICAL SOCIETY.—"At the recent annual meeting the following-named gentlemen were elected officers for the

ensuing year: President, Dr. P. Albert Morrow; Secretary, Dr. W. T. Alexander; Treasurer, Dr. F. D. Weise; Executive Committee, Dr. R. W. Taylor, Dr. E. B. Bronson, and Dr. G. H. Fox.

THE WOMAN'S MEDICAL COLLEGE OF THE NEW YORK INFIRMARY.—The following-named ladies were graduated at the recent commencement: Augusta A. Field, of Pennsylvania; Julia G. F. McNutt, of New York; Sarah R. Mead, of New Jersey; Harriet Post, of Wisconsin; and Maria B. Patterson, of New York.

THE AMERICAN SURGICAL SOCIETY AND THE CODE QUESTION.—At the annual meeting of this society, held in Cincinnati last week, on motion of Dr. Kinlock, of South Carolina, the secretary was directed to communicate with every member, asking him his views on the code question, and, in case he was not prepared to support the code of ethics of the American Medical Association, requesting him to resign.

THE MARINE HOSPITAL EXAMINATION.—The following-named applicants are announced as having passed the examination: Dr. Arthur D. Bevan, of Chicago; Dr. A. H. Glennan, of the District of Columbia; Dr. Eugene Wadsen, of South Carolina; Dr. K. P. Battle, of North Carolina; Dr. S. D. Brooks, of Massachusetts. There being only one vacancy, it is understood that Dr. Bevan will receive the appointment, the others to wait for vacancies in the order mentioned.

THE CARE OF THE INSANE IN PENNSYLVANIA.—The Pennsylvania Senate has passed the House bill providing for the removal of the indigent insane from almshouses to State hospitals.

A PROPOSED VACCINE INSTITUTION IN PARIS.—The sanitary council of the Department of the Seine have appointed a commission to devise a plan for the establishment of an institution for supplying vaccine in Paris. The actual realization of the scheme, however, requires the approval of the administration.

DR. ROOSA'S RESOLUTION ANTICIPATED.—Our attention has lately been called to an address delivered before the Maine Medical Association in June, 1880, by the president, Dr. Seth C. Gordon, of Portland, in which we find the following passage:

"Now and then we find the man of age and experience who looks upon the younger members as intruders, and, like the 'Pine Ridge practitioner,' treats them strictly according to the code. For such men are codes made, and, so long as the profession contains many of them, I suppose we must have our written law. I shall hope to see the day when much of the present code of ethics adopted by the American Medical Association may be expunged, and each man become a law unto himself. The military profession has comparatively few written statutory laws defining and punishing offenses. There is a certain *esprit de corps* which puts every man upon his personal honor in all his relations with his brother officers and the world about him. The general charge of 'conduct unbecoming an officer and a gentleman' covers a very large majority of all misdemeanors. The golden rule, of doing unto others as you would that they should do unto you, is the foundation of the best code of ethics that any body of men could adopt. Will the time ever come when 'conduct unbecoming a physician and a gentleman' will have as much meaning and as much force in our profession as the former has with our 'brethren in arms'?"

"Our sister State (or, more properly, our venerable mother, Massachusetts, has taken a step in the right direction on this matter of code—very much simplifying and abbreviating the old law. May we not do something in the same way to our advantage? There are certainly some things we should all agree upon. I would suggest that a written law often gives a dishonorable man an opportunity to try its full strength, and, without actually breaking it, he violates the spirit, leaving the 'letter which killeth.'"

"**VENUS DE MEDICINE**" is what the "Florida Herald" calls the late Lydia Pinkham.

DEATH OF DR. JAMES L. BANKS.—We regret to have to record the death of Dr. James Lenox Banks, which took place on Sunday, the 3d inst. Dr. Banks was one of the consulting physicians to the Presbyterian Hospital, and a member of many medical societies, in which, as well as

in matters not connected with the profession of medicine, he filled positions of trust and responsibility at various times. As a practitioner and as a man, he enjoyed the esteem and respect of all with whom he came into contact. At the time of his death he was fifty-one years of age. He had seemed to be in good health until within a week of his decease, which we understand to have been due to an attack of apoplexy.

DEATH OF DR. WOLCOTT, OF UTICA.—Samuel Gardner Wolcott, M. D., of Utica, N. Y., died on Sunday, the 3d inst., in his sixty-third year. Dr. Wolcott received his degree in medicine from the Harvard Medical School in 1850. He was one of the prominent physicians of the central part of the State.

DEATH OF DR. ROBERT DRUITT.—Robert Drutt, M. D., F. R. C. P., F. R. C. S., well known in this country as the author of "The Surgeon's Vade-Mecum," a book that for many years past has been very popular with students, died at his home in London on the 15th of May, at the age of sixty-eight years. For a period of ten years Dr. Drutt was the editor of the "Medical Times and Gazette," which journal speaks in feeling terms of his decease.

ARMY INTELLIGENCE.—*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from May 26, 1883, to June 2, 1883.*—HEGER, A., Major and Surgeon. Assigned to temporary duty in charge of the office of Medical Director, Department of the South, during absence on sick leave of Medical Director. Par. 9, S. O. 55, Department of Texas, May 24, 1883. — BROWN, PAUL R., Captain and Assistant Surgeon. The extension of leave of absence on surgeon's certificate of disability granted November 23, 1882, further extended six months on account of sickness. Par. 6, S. O. 123, A. G. O., May 29, 1883.

NAVAL INTELLIGENCE.—*List of Changes in the Medical Corps of the Navy during the week ending June 2, 1883.*—Passed Assistant Surgeon D. O. Lewis detached from the McArthur, United States Coast Survey steamer, and ordered to the Marine Rendezvous, San Francisco, Cal. — Passed Assistant Surgeon F. C. Dale ordered to the United States Coast Survey steamer McArthur. — Medical Directors J. M. Browne and A. L. Gihon ordered as delegates to the meeting of the American Medical Association at Cleveland, Ohio, June 6, 1883.

SOCIETY MEETINGS FOR THE COMING WEEK.—*Monday, June 11th:* New York Medical-Historical Society; New York Ophthalmological Society (private). *Tuesday, June 12th:* Massachusetts Medical Society (Boston—first day); Jersey City Pathological Society; Newark Medical Association; East River Medical Association (private); New York Academy of Medicine, Section in Surgery; New York Surgical Society; Medical Society of the County of Chenung, N. Y. (Elmira—annual); Medical Society of the County of Chenango, N. Y.; Medical Society of the County of Delaware, N. Y. (annual); Medical Society of the County of Erie, N. Y. (Buffalo); Medical Society of the County of Genesee, N. Y. (annual); Medical Society of the County of Livingston, N. Y. (Genesee—annual); Medical Society of the County of Onondaga, N. Y. (Syracuse—annual); Medical Society of the County of Oswego, N. Y. (Mexico—annual); Medical Society of the County of St. Lawrence, N. Y. (semi-annual); Medical Society of the County of Schenectady, N. Y. (Schenectady—semi-annual); Medical Society of the County of Steuben, N. Y. (Bath—annual); Medical Society of the County of Warren, N. Y. (Lake George—annual); Medical Society of the County of Wyoming, N. Y. (Warsaw—annual). *Wednesday, June 13th:* Oregon State Medical Society (Portland—first day); Massachusetts Medical Society (second day); New York Pathological Society; Medical Society of the County of Cayuga, N. Y. (annual); Medical Society of the County of Cortlandt, N. Y. (annual); Medical Society of the County of Dutchess, N. Y. (Poughkeepsie); Medical Society of the County of Montgomery, N. Y. (annual); Medical Society of the County of Sullivan, N. Y. (Monticello—annual). *Thursday, June 14th:* Oregon State Medical Society (second day); Brooklyn Pathological Society; Medical Association of the Eastern District of Brooklyn; New York Laryngological Society (private); Public Health Association. *Friday, June 15th:* Oregon State Medical Society (third day).

Original Communications.

THE CLIMATIC TREATMENT OF PULMONARY CONSUMPTION; REPRESENTING THE OPINIONS OF THE PROFESSION IN REFERENCE TO CLIMATOLOGY AND CONSUMPTION.

By J. HILGARD TYNDALE, M. D.,

NEW YORK.

(Continued from page 629.)

MIDDLE ATLANTIC STATES.

Dr. Austin Flint, New York, kindly referred me to his work on "Phthisis" (1875): "In the first place, it does not appear from the analysis of my cases [670 cases of phthisis] that changes of climate have, in a marked degree, a beneficial influence, as compared with the hygienic measures available at home. In the second place, the improvement following a change appears to pertain alike to different climates and places. Hence it seems a fair inference that the benefit derived from the change is due, not so much to a climatic influence, *per se*, as to the circumstances incidental to the change. . . . Now, the climate in itself is of secondary importance; assuming, of course, it to be *salubrious*, all the conditions of salubrity may be combined in numerous places situated in either a northern or southern latitude. It is not essential to canvass the respective claims of different places in respect of climatic conditions, after having decided whether a cold or a warm climate is to be preferred. . . . Whether a cold is to be preferred to a warm climate, in particular cases, must depend upon the predilections of a patient, the past individual experience as regards the relative effect of cold and warm weather on the feelings and the general health, the ability to take muscular exercise, the power of resisting or reacting to cold. . . . *It may be presumed that a warm climate is best suited to a majority of cases.* . . .

"A favorable influence upon phthisis is exerted by a variety of climates. It would seem that the favorable influence pertains to the change rather than to the particular climate chosen. If this be true, it follows that the agencies by which a favorable influence is exerted *relate to accessory or incidental circumstances* more than to purely climatic conditions."

Dr. A. L. Loomis, New York, says, in the latest edition (1882) of his "Diseases of the Respiratory Organs": "Experience shows that one individual improves in a warm, moist air; another individual improves in a cold, dry air. . . . When, from the history of the individual, a *dry, cold atmosphere* is indicated, direct your patient to make a trial of such a climate as Minnesota. . . . Let none go to Minnesota who are unable to exercise in the open air. The climate of California (especially southern California), Colorado, certain parts of Georgia, South Carolina, etc., is well adapted to that class of phthical patients who require a *dry, warm atmosphere*. . . . The experience of the indi-

vidual is the only safe guide in the choice of a locality best suited to his or her own case. . . ." [Of Colorado]: "Persons in the incipient stages do well; but the air is so thin and dry that it is very likely to cause hæmorrhages in those cases where they have previously existed. . . ." [Of Georgia and the pine forests]: "Undoubtedly have very much to do with the beneficial effects experienced. . . . When you decide, from the experience of a phthical patient, that a *warm, moist climate* is required, let him go to the Bermudas, or to some of the West India islands, or to the eastern portion of Florida. Under the head of a *cool and moderately moist climate* I know of no region that my experience during the past few years of its effects upon phthical subjects would lead me more heartily to recommend to those likely to be benefited by such a climate than the Adirondack region, situated in the northern part of our own State. . . . *The climatic treatment of consumption is almost exclusively confined to its first stage.* . . . Frequent changes of climate are all-important in order to accomplish this result. During this stage, sometimes patients will be benefited by a long sea voyage."

Dr. Beverley Robinson, New York: "I favor a sthenic climate where the affection is not far advanced and where tendency to hæmorrhage is slight and recuperative power good. Georgia in winter; Adirondacks in summer."

Dr. Samuel G. Armor, Brooklyn: "In cases of *primary tuberculosis*, phthisis in which the constitutional symptoms of malnutrition outrun the local lung lesions, I prefer a dry, stimulating, tonic atmosphere, such as is found in Minnesota, Dakota, Montana, New Mexico, or the eastern slope of the Rocky Mountains. Above all things, such cases need a *dry, bracing, appetizing climate*. For *primary catarrhal phthisis*, in which the alveolar catarrh is the *prime factor*, the constitutional symptoms developing themselves as a sequence, I prefer a mild, soothing, sedative climate, in which the patient can live much of the time out doors. I advise such patients, when they can, to go to northern Georgia, southwestern Texas, some portions of California, etc. I am not partial to Florida."

Dr. H. D. Didama, Syracuse, N. Y.: "Some patients are so much debilitated by warm weather and feel so much better in cold weather, that I never think of sending them to Florida or Nassau. If I send them away from our delectable and variable climate, where the thermometric ranges are from 15° to 40° daily, I advise some cool, equable region. Some go to Minnesota and some to Colorado with benefit. In summer, our own neighborhood, or the North Woods, or Thousand Islands afford all that is needed. If, on the contrary, the patient feels worse as cold weather approaches, if he is pinched and unable to keep comfortable, I do not send him to the frigid zones. He goes to some milder clime, if he can afford it, or I try to make a uniform climate at home, if, as unfortunately happens, he can not afford to travel. But in the artificially equable climate in his house in bad weather, I would have the air supplied with moisture enough, so that the thirsty, dried, clamorous atmosphere would not suck all the juices of the patient away. These are briefly some of my rules:

"1. If possible, make a change early.

"2. Go where the temperature is satisfactory to the patient—inigorating or soothing, as the case may be.

"3. In incipient cases with bronchial catarrh in apex, a mountain elevation and proper instructions will, by securing chest expansion, do good.

"4. Home for the hopeless."

Dr. William T. Plant, Syracuse: "I incline to the sthenic climates for *incipient phthisis*. I think *very few actual* consumptives recover in Florida or the West Indies. Many recover in Colorado, Minnesota, etc. My opinion on this point has been formed from considerable observations, extending over eighteen years. I have directed patients to the elevated and dry regions of the far West rather than south to the Atlantic States. The result has almost always been gratifying when the patient has gone early. I have *known* several consumptives to go *early* to Florida, Nassau, etc., and they have never done well. Some have come back after a few months and gone West, where they improved. I think it quite likely that *some* cases are benefited by leaving our rigorous climate and making of Florida a *winter residence*."

Dr. Louis Elsberg, New York: "A sedative climate for patients with sensitive mucous membranes; a sthenic climate for catarrhal tendencies. In summer to Adirondack Mountains, Catskills, or, at least, where there are trees, horseback exercise, and animal food. In winter, southern equable climates, where the same requisites of beef, air, and exercise can be supplied."

Dr. Daniel Lewis, New York: "My experience is against sedative climates. The inland medium altitudes are most suitable. I send all to the eastern slope of the Rocky Mountains, if they are able to go. Some have done very well in Minnesota. Results are much the same, as in all therapeutic measures; some are benefited and others are not. I have some cases, of several years' duration, who have spent winters here and summers in the Adirondacks, and the disease is still stationary. One case remained well three and a half years in Alleghany County, N. Y., fifteen hundred feet above sea-level. Of one thing I am positive—results have been bad on the sea-coast in warm or cold climates."

Dr. Alfred Stillé, Philadelphia: "I believe that cold climates are suitable for commencing and warm for confirmed phthisis, and that sea air, except in warm climates, is, as a rule, prejudicial to all cases of consumption (tubercular). I advise a climate mild, equable, and dry. The dryness and steadiness of the places named appear to me their best qualities. [The places named were Florida, Madeira, the Bahama Islands on the one hand, and Minnesota, Colorado, New Mexico, Georgia, Texas, and California on the other.] I have usually sent the vigorous to a cold, the delicate to a warm climate. As far as possible, rapid transitions from one to the other are to be avoided, but especially from cold to heat. On the whole, I think the results of change of climate are superior to all others."

Dr. J. Solis Cohen, Philadelphia: "My habit has been to notice how the different seasons and atmospheric conditions affected the patient when at home, and to endeavor

to find a climate corresponding with the indications thus obtained. *Sea air before softening; mountain air after softening*. In the majority of cases, a cold temperature is desirable; but it must be governed by the comparative comfort of the patient under similar conditions at home. Dry, bracing climates (New Mexico, Colorado) are suitable to a majority. Always avoid sea-shore if there has been any breaking down of tissue. Send lately to Lakewood, New Jersey; to Aiken, Southern California, Mexico, and Adirondacks, even in winter. The point upon which I desire to lay most stress is this: *That sea air should be rigorously avoided as soon as there are any signs of softening in the lungs or ulceration in the larynx*."

Dr. J. C. Wilson, Philadelphia: "For a minimum of my cases I prefer a sedative climate; for the majority a stimulating, sthenic climate. Certain insular elevated stations are of importance: Madeira, Capri. Direct patients to Las Vegas and Santa Fé, N. M., and to Aiken, S. C. Patients are less disposed to follow my advice than their own wish in summer."

Dr. E. T. Bruen, Philadelphia: "I regard the cold, dry climates at a high altitude as most beneficial for incipient phthisis, or for advanced cases, provided there is no history of hæmorrhages or much catarrhal trouble. These latter cases do better in the warmer climates near the coast. The advantages of the climate of the great West—of the Mississippi—are much depreciated by the bad hotel accommodations. Only a few localities are satisfactory on this account. A majority of cases will be most benefited by a dry, sthenic climate—Adirondacks, New Mexico, southern Colorado, northern Texas. But a large minority will be helped by such latitudes as northern Georgia or the Mediterranean. Climato-therapy with suitable food is the most satisfactory kind of treatment."

Dr. Roberts Bartholow says in his "Treatise on the Practice of Medicine" (1882): "The requisites for a climate for pulmonary invalids have been briefly stated. They are *dryness* and *elevation*. The health resorts which offer these requisites in the highest perfection are the best. Those of North Carolina, South Carolina, Georgia, the Rocky Mountain regions, California, New Mexico, offer every variety. No change of climate, however, can be beneficial, as a rule, after cavities have been formed, unless of slight extent. It is in incipient phthisis that a change to a climate dry, bracing, and elevated, really exerts a curative influence."

Dr. Samuel C. Chew, Baltimore: "I prefer, from experience, so-called sthenic climates. Send patients to mountainous regions of North Carolina and to the Adirondack Mountains in New York. Think it best, generally, to remain winter and summer."

Dr. Richard McSherry, Baltimore: "In February, March, and April, as the winter breaks up, Florida offers a good climate. No uniform rule as to directing patients. Some to Florida, some to the mountains. A consumptive, who has leisure and money, and can change his location at discretion, and does so with discretion, seeking now a cool and dry climate, and then the sea-shore, or taking a sea trip, may enjoy a modicum of health for many years."

Dr. A. Y. P. Garnett, Washington: "I prefer for those

disposed to or threatened with the disease a mild or sedative climate, such as that found in Madeira, Bahama Islands, Los Angeles, and, perhaps, some of the piney hills of Florida, remote from the sea and bodies of water. Where the disease has become sufficiently manifest to be detected by physical or rational signs, a sthenic or bracing climate, such as found in Minnesota, some parts of New Mexico, and other dry and elevated situations; the South Pacific Ocean when practicable."

SOUTHERN STATES.

Dr. F. Peyre Porcher, Charleston, S. C.: "I would prefer in winter a climate like Aiken, or any dry, warm climate, with a porous soil, where water escaped readily; where there was sunshine and freedom from cold winds, as also is the case with pine-land settlements, and even the plantations along the coast of South Carolina and Georgia. . . . Aiken or Florida in winter; Asheville, or any cool mountain plateau, in the summer. The climate, in the winter, of the plantations on the Atlantic sea-board of South Carolina and Georgia, within fifty miles of the coast, is, I think, excellent; the 'pine-lands' perhaps better, though uninteresting."

Dr. Deering J. Roberts, Nashville, Tenn.: "A sedative climate only in advanced cases; a sthenic climate in early stages. I am in the habit of directing my patients to the *Cumberland table-land*."

Dr. J. G. Westmoreland, Atlanta, Ga.: "I favor a sedative climate. The sthenic climates are too high and cold, but better, with plenty of oily food, than warm climates without such food. Send patients to Florida or tropical islands. Would prefer keeping the same temperature summer and winter."

OHIO VALLEY.

Dr. Starling Loving, Columbus, O.: "If the patient is of sanguine or extremely nervous habit, I prefer sea air, the 'sedative climate.' Direct patients to Colorado, Minnesota, North Carolina, north Alabama, Thomasville, Ga., Nassau, and the south side of Cuba. I sent one to San Antonio, Tex., and regretted it. One has done well at Boise City, Idaho, and two or three in Wyoming. The climate here in winter is damp and exceedingly variable, so that I urge patients, whether going North or South, to go in November and not to return until the middle of April. I have known several greatly benefited by the climate of southwestern Kansas."

Dr. James T. Whittaker, Cincinnati: "Experience teaches me to prefer Nassau to all southern climates; because it is a pure sea air is the reason for the good effects, I believe. For other cases—the higher and colder the better, if general comfort can be secured—Colorado, about Denver. If I had the disease myself, I should, in the light of existing knowledge, go and *live* in the coldest, driest climate I could find, as in Switzerland near the line of perpetual snow. Of course, the disease exists there, but because, I believe, people live in-doors with artificial heat."

Dr. George E. Walton, Cincinnati: "Am opposed to a relaxing climate. Of sthenic climates, prefer northern Georgia, Aiken, S. C., Texas, southern California. Direct

patients to Mentone or Aiken during winter; summer, Colorado, Minnesota, Catskills. Unfortunately, we have not the meteorological facts or medical facts to make valuable conclusions."

Dr. D. N. Kinsman, Columbus, O.: "Favor a stimulating, tonic climate. Direct patients to the Northwest. My experience has not been very favorable."

Dr. H. von Sweringen, Fort Wayne, Ind.: "I most emphatically favor that climate which is marked by an *evenness* of temperature, even though it be a little too cold in winter or too warm in summer. Florida in winter, the North in summer. I have never given any *special* attention to climato-therapy in the treatment of phthisis, for the reason that I have never had very much confidence in it. The more *temperate* the climate, however, the less disposed to *rapid* and *great* variations of temperature, the better, certainly, for consumptives."

Dr. L. P. Yandell, Louisville, Ky.: "No faith in Florida. I should prefer the dry climates of parts of Texas and New Mexico—wherever there is least malaria. Considering the vast advantages of being sick at home, rather than at poor hotels away from home, the superior household and culinary comforts of home, I usually prefer to keep my patients at home. I consider the majority of cases of consumption curable by means of the constructives, i. e., oils internally and externally, hypophosphites and maltine, and tempting foods. This is my experience in private practice here."

Dr. John J. Speed, Louisville: "Eastern slope of the Rocky Mountains and northern Georgia good; but the *want* everywhere is equable climate. Direct patients to the climate which is cool and equable. If not equable, you can not *use* it; and this use gives you sunlight, fresh air, and out-door life, which three factors are the prime ones. Stimulated nerve-force, stronger heart-beat, deeper chest-expansion are had, and these give increased appetite and better nutrition."

Dr. M. F. Coomes, Louisville: "I am in favor of such a climate as is found in the orange-belt of Florida; I also favor the so-called sthenic climates for certain cases. From November to May I recommend them to go to the orange-belt of Florida (*Palatka, Deland, Gainesville, and Fort Mead*), or to the temperate portions of *California*; and I occasionally advise my patients to make these localities their permanent homes, if the climate is particularly agreeable to them. From May until October or November I recommend them to Red Sulphur Springs, in West Virginia, where they get the mountain air and the benefits of the water. Also to Minnesota, New Mexico, or Colorado. In many cases I recommend them to change their homes twice a year."

LAKE REGION.

Dr. Thomas F. Rochester, Buffalo, N. Y.: "A cool and equable climate is the best, with some exceptions. I have had better results in southern California than elsewhere; next in Colorado, and fair in the Adirondacks, which are high but moist. I am inclined to believe that the enforced exercise treatment (as at Davos) is a very important factor in the treatment."

Dr. H. R. Hopkins, Buffalo: "In certain cases a seda-

tive climate; in general, not. Give preference to sthenic climates (those mentioned in my circular). Dryness, sunshine, and purity of air do the work, in my opinion."

Dr. John Bennett, Cleveland, O.: "Prefer a sthenic climate; Colorado (Denver, Golden, etc.), southern Minnesota, pine regions of South Carolina, away from the lowlands. East Tennessee when practicable. Advantage, more or less permanent, has been observed to come from removal to each of the places named, where the residence has been long enough to be in any degree a test."

Dr. H. J. Herrick, Cleveland, O.: "I am in favor of the climate of western and northern Texas, Colorado, the mountains of the Carolinas or northern Georgia. Am in the habit of directing patients to the above localities. I regard out-door life, with prudent exercise and correct diet, important considerations in the treatment of incipient tubercular phthisis."

Dr. E. L. Shurley, Detroit, Mich.: "From experience, I believe a sedative climate more beneficial for cases characterized especially by terrible cough. Do favor a stimulating climate where air is dry and changes of temperature, etc., are not great. Direct patients to no particular locality, but decide according to condition of the patient, accommodations of the place, previous mode of life, predilections of patient, etc. Temporary residence in favorable climate has, according to my experience, only temporarily prolonged life where real phthisis existed, while a permanent residence has evidently effected a cure in many cases."

Dr. David Inglis, Detroit, Mich.: "Favor a stimulating, ric climate: Texas and southern California. When possible, advise permanent residence in such climates; when not, advise to go by November 1st, and *not to return North until well into June*. The general mistake is in coming North too early in the spring. Unless the patient goes before the third stage has set in, and also unless he has sufficient vigor to engage in considerable out-of-door exercise, it is better for him to remain amid the comforts and attentions of home."

Dr. N. S. Davis, Chicago: "For some patients, a sedative climate; for the majority of cases, a sthenic one. I regard a judicious change of climate in the first stage of consumption of the highest value in arresting the progress of the disease. But the change should be *long-continued*, in order to render the effects permanent."

Dr. H. M. Lyman, Chicago: "The mild climates are useful when patients have been long imprisoned in-doors by a severe northern winter; but for a permanent residence the inland regions are preferable. Direct patients to Colorado and New Mexico, unless it be desirable to go South for the reason above mentioned."

Dr. E. Fletcher Ingals, Chicago: "In a few cases *only* I prefer sedative climates, but in the great majority of cases of early (first and second stage) consumption I much prefer the 'sthenic' climate. According to the indications in individual cases, as judged by their apparent vitality, the bronchial affection and past history, I direct them to most of the regions mentioned. But the majority are sent to Colorado, New Mexico or Arizona, Texas, southern California, Tennessee, Georgia, Minnesota, and Florida.

These I have given, as nearly as possible, in order of frequency."

Dr. J. N. Danforth, Chicago: "I prefer a cool climate, with some constant incentive to exhilarating exercise. With my phthisical patients any change is tentative, and they so understand it; but a sthenic climate seems to benefit the greatest number. Travel, change, novelty, and the consequent excitement, generally benefit, and, I think, form the main parts in climato-therapy."

Dr. James P. Ross, Chicago: "Favor a stimulating, tonic climate—southern California or San Antonio, Tex. I send patients away in winter and spring."

Dr. Roswell Park, Chicago: "Prefer sthenic climates. I tell patients to go where the conditions of a *temperate* climate, with proper *dryness* and freedom from sudden changes, can be found, no matter if the locality has no 'reputation.' I like the mountain region of Tennessee."

Dr. Alonzo B. Palmer, Ann Arbor, referred to his recent work on "Practice of Medicine," in which he says: "There must be a certain good degree of digestive power, or a prospect of soon obtaining it. . . . Comparative youth and vigor are required. In comparatively early periods of chronic cases there can be no doubt of the beneficial effects of elevated, dry, cool, electrical, stimulating, climatic situations (Rocky Mountains, Col.). For those more impressible and delicate, New Mexico. In bronchial, pneumonic, and other inflammatory cases, a sojourn in Florida, Santa Barbara, or Georgia. In the treatment of ordinary cases of chronic tuberculosis, *cool* and *dry* climates give better results than *warm* and *moist*. A particularly equable temperature must not be insisted upon except in bronchial and inflammatory cases, as equability presupposes moisture, which is far less favorable to the tuberculous condition."

THE NORTHWEST.

Dr. Jay Owens, St. Paul, Minn.: "Do not favor a sedative climate. Florida is covered with consumptives' graves. A sthenic climate, such as Minnesota in summer, and the Valley of the Rio Grande River, in New Mexico, in winter. Dryness is the great curative factor. Patients do not take cold in a dry atmosphere, if they are reasonably careful. From personal experience, I know a *dry* atmosphere to be of great advantage. I know of many cases of recovery by those afflicted coming to Minnesota early in the disease. I send my patients to Socorro, N. M., in the winter, and they come back much improved."

Dr. Alexander J. Stone, St. Paul: "I prefer in certain cases your so-called sthenic atmosphere, varied, according to condition of patient, from the warm, dry, and pure air of the Georgia Highlands to the cooler, more bracing (tonic) atmosphere of Colorado, Minnesota, or, most notably, *Montana*. The majority of cases met with in Minnesota are imported, and remain here; occasionally one finds the climate unsuitable, and is sent northwest or southeast, as indications determine. Aboriginal cases are always sent from home."

Dr. D. W. Hand, St. Paul: "Favor a sthenic climate. Direct patients to Las Vegas, N. M.; Aiken, S. C.; Thomasville, Ga."

Dr. George F. French, Minneapolis, Minn.: "Sedative

climates for hæmorrhagic cases. Have saved a wife, pronounced incurable by several eminent diagnosticians, by changing climate from Portland, Maine, to Minneapolis. Here three years."

Dr. W. S. Robertson, Muscatine, Ia.: "Prefer the medium altitudes of New Mexico and Colorado: the country around Colorado Springs and Manitou. Dryness is an important element (most important). The climate spoken of has given me excellent results. Don't think any of these are life-giving, but life-prolonging localities."

Dr. W. I. Heddens, St. Joseph, Mo.: "From experience, I prefer a mild climate for advanced cases—Florida. A 'stimulating tonic' for incipient cases, as New Mexico, Colorado, California—where a dry, cool atmosphere exists—avoiding all 'health resorts' and cities. Of the results of climatic treatment: *Only in the very incipency*, and, I may say, before that even, is it at all reliable, and in the advanced stages it hastens the death of the patient."

MISSOURI AND MISSISSIPPI VALLEY.

Dr. E. W. Schaufler, Kansas City, Mo.: "Generally the stimulating climates. Should think the mild climates might suit the advanced cases better. Dryness is a most potent factor, with abundance of sunshine. Do not think the winds do very much harm. Direct patients chiefly to Colorado Springs, Col."

Dr. P. Gervais Robinson, St. Louis: "I favor a stimulating, tonic climate at medium altitude, my opinion being based both on experience and principle—northern Georgia and South Carolina—Aiken, S. C., in winter, Minnesota in summer. The results of my experience are very encouraging."

Dr. William C. Glasgow, St. Louis: "I look for the fresh, stimulating, tonic air; tonic and stimulating to improve the general bodily nutrition, and sufficiently rarefied to cause an increased and full expansion of the air vesicles. I have not accepted the 'germ theory.' I consider the soft, mild climates (humid) as disastrous to cases of real phthisis: they suit bronchitis and uncomplicated laryngitis. I prefer always a stimulating, dry climate. The choice of high altitudes or lesser degrees of elevation depends on the individual case. When general inflammation of mucous membranes is present, I consider the high altitudes positively injurious. Cases with laryngitis do badly in Colorado. For such cases I prefer the highlands of Texas, and, after this, southern California and northern Georgia. Where malnutrition and want of bodily vigor are prominent factors, I like a short stay in high altitudes, then a continued stay at a moderate elevation—three thousand to four thousand feet. Besides the above named, direct patients to New Mexico and Minnesota. I like patients to change climates—summer in one place, winter in others. I never send a patient away from home with *acute symptoms*; subdue these, start arrest, and then he is ready to travel. I consider an important factor in the choice of a climate to be in the possibility of obtaining good, digestible food and cheerful society or amusement, also of obtaining light employment. My experience has been favorable. Some cases seem absolutely arrested, in others life has been prolonged by years. The highlands of Texas

have given the most favorable results; next, New Mexico and southern California. But the cases must be sent to proper climates, and must absolutely renounce a return to the home climate. They are exiled from home. Even a prolonged visit to the home climate has, in my experience, relit the disease."

Dr. G. Baumgarten, St. Louis: "Soothing climate only for nervous persons. Have seen good results from parts of Texas; also some good, and more very bad, results from Colorado, the latter in nervous persons and nervo-sanguine. As much depends upon the nature of the home to be avoided as the climate to be sought. I frequently send a patient away from home in winter in order to *avoid* the particular winter climate of his home. In general, I can say that I have seen few successes that I should ascribe to the climate."

LOWER MISSISSIPPI VALLEY.

Dr. Heber Jones, Memphis, Tenn.: "Favor a soothing climate for certain cases. Of sthenic climates, the less elevated stations. Florida and Texas in winter, and cooler climates (suitable) in summer. Broadly speaking, I am satisfied that the disease is often arrested in the incipient stage, and, if the change is made later, life is prolonged."

Dr. P. O. Hooper, Little Rock, Ark.: "Prefer mountain, rather upland, not necessarily very elevated. Certain parts of Texas preferable; at or near Austin, Texas (west). General results of experience very favorable."

Dr. Stanford E. Chaillé, New Orleans: "Favor stimulating, tonic, so-called sthenic climates. Direct patients to neighborhood of Asheville, Buncombe County, North Carolina. Results of experience: Much more favorable to mountain climates than to any other remedies."

Dr. Samuel M. Bemiss, New Orleans: "Prefer a stimulating, tonic climate. Direct patients to northern Georgia, southern California, western and northwestern Texas, North Carolina, gulf coast of Mississippi, and Mexico (Oaxa). General results: Average favorable to prolongation; cures more frequent."

In order to make this report as complete as possible, the opinions of certain gentlemen will be given who practice in the center of such regions as we know to be of benefit to the various forms of phthisis, the chief object being to have them set forth the advantages of *elevation, dryness, and equability*, respectively.

1. MARINE CLIMATE.

Equability of temperature. No dryness. No elevation.

FLORIDA.

Dr. Frederick D. Lente, Palatka: "Experience teaches me to prefer a *warm and moderately dry* climate. The ideal climate should neither be too dry nor too equable, very dry climates being subject to great diurnal range of temperature. The indications are that the profession are arriving at the conclusion that the climate which will offer the greatest inducement to invalids to be out in the open air, or which will enable them to *breathe in constantly and without danger of chilling the surface*, or, in other words, that which furnishes the *greatest amount of pure air*, is the one to be preferred. . . . I do not believe elevation to be a necessary

factor, nor do I attribute any influence to the reduced pressure of the air-column at high altitudes. With regard to *elevated regions*, it is worthy of note that, in almost all if not all of them, diseases of the respiratory organs are very prevalent.

The benefits of warm climates consist in this, that outdoor exercise can be indulged in with less chance of in any way lowering the vitality. *This is the gist of the whole matter of climate.* A moderately warm and moist climate like that of Florida is best, because nearly all invalids shrink from moderate degrees of cold, and, even if they have sufficient vitality, have not enough energy to brave any considerable degree of cold, day or night.

The mean winter temperature (six months) in Florida is about 63° Fahr., and during five sixths of the days the sun shines brightly. The climate of Florida ought not to be classed with that of Nassau or Madeira. It is peculiar, and a person, to appreciate its peculiarities fully, must spend a winter, and, if it be an exceptional winter, more than one. The dampness and malaria, for instance, have been much exaggerated. One peculiarity, which I think renders it superior to tropical climates, and prevents their curative effects, are the frequent changes of temperature, the range being insufficient to affect the most delicate invalid unfavorably, but enough to obviate debility and the debilitating effects of an invariable temperature, to which some places approach (as the Isle of Pines), but do not attain. . . . Of course, there are here, as in other States, healthy and unhealthy areas, and areas where the *summer* heat is found to be intolerable. It behooves those wishing to make Florida a *permanent* residence to look well to this circumstance. But tourists and the great majority of invalids are only concerned with the *winter* climate of Florida.

The tables of *relative humidity* give no correct idea of climatic humidity. . . . Palatka is undoubtedly a drier climate than the stations on the river farther north; fogs less frequent and less persistent. . . . Those who seek anxiously for *dry* climates overlook the fact that a *certain degree* of moisture in the air is absolutely necessary to prevent a great diurnal range of temperature, which these persons equally deprecate. In Florida, for instance, were it not for a certain amount of moisture in the air, and a certain amount of deposit of dew, would have a fall of 30° or 40°, instead of 13° or 14°.

The hilly country of middle and southern Georgia do well for some invalids—those that can stand a considerable degree of cold, and go out of doors at all times.

With regard to the proper time for going to Florida, one may go from the first to the middle of November, if his condition requires so early a retreat from inclement weather.

There are many cases, especially the advanced cases, which do better by remaining here summer and winter, and get worse, even in summer, if they go north."

(To be concluded.)

THE MEDICAL PROFESSION AND PUBLIC INSTRUCTION IN ITALY.—It is worthy of note that the Superior Council of Public Instruction includes among its members no fewer than four medical men: Bizzozero, Cantani, Alfonso Corradi, and Ercolani.

A CASE OF PRESENTATION OF THE HEAD, HAND, FOOT, AND CORD.*

By HENRY J. GARRIGUES, A. M., M. D.,

OBSTETRIC SURGEON TO MATERNITY HOSPITAL, NEW YORK.

Mrs. ELIZA H., septipara, about thirty-five years old, was delivered, on the 26th of February last, in the Maternity Hospital. In her first labor, twelve years ago, she had sustained a laceration of the perineum extending through the external sphincter ani muscle into the rectum, which had been left without treatment, and yet remains.

She had been for some time in the waiting ward, but had concealed that she was in labor, which the women sometimes do, hoping thereby to avoid the transfer to the delivery-room and the lying-in wards. When finally another patient called attention to her sufferings, it was found that a long loop of cord protruded from the vulva. Further examination revealed that the head was at the brim in the left occipito-posterior position, and that the right hand and the right foot, with part of the leg, had come down beside and in front of it, and were surrounded by loops of the still pulsating cord. Meconium was pouring out of the os, which was about three fourths dilated and dilatable. All the liquor amnii had escaped, and the patient suffered severe pain. She was seven months advanced in pregnancy.

The patient was placed in the knee-elbow position, and a vain attempt was made at reposition by one of the staff before my arrival. Then she was turned on her back and put under the influence of chloroform. The vagina and external genitals having been thoroughly disinfected with five-per-cent. carbolyzed water, the presenting foot was with difficulty separated from the surrounding coils, drawn a little down, and caught in a fillet round the ankle. During these manipulations the pulsation in the cord stopped. I tried in vain to dislodge the head by moderate traction on the fillet and direct pressure on the head from the vagina and from the abdomen. I therefore introduced the left hand into the womb, easily got hold of the other foot, drew it down into the vagina, and put a fillet on it. By traction on this, combined with pressure on the head, the latter was dislodged without any difficulty.

The body was easily extracted to the shoulder-blades. The loosening of the anterior (or right) arm gave some little trouble. After that had been brought down, the posterior (or left) arm was brought down with great ease. The extraction of the head met with a slight arrest, caused by the incomplete dilatation of the neck. Not succeeding in extracting it by the Prague method (the finger of one hand spread over the shoulders, the other grasping the feet and drawing them up over the mother's abdomen), I resorted to Levret's method (a finger in the mouth, those of the other hand on the shoulders). Upon the whole, the operation was an easy one, and would probably have resulted in the birth of a living child if the case had come under treatment in time. The child weighed seven pounds. The mother is doing well.

The presentation of head and foot is rather rare, and

* Read before the New York Obstetrical Society, March 6, 1883.

occurs mostly with premature children, as in our case, or with dead and limp children, or after unsuccessful attempts at delivery by version. Dr. Henry G. Landis, of Columbus, Ohio, wrote an interesting article on the subject in the "American Journal of Obstetrics" last year (vol. xv, p. 127 *et seq.*), reporting three cases from his own practice, all involving the death of the child, and one in that of Dr. Loving, of Columbus, the latter differing from most of the reported cases in the birth of a living child.

In the same volume (p. 434) is found a paper on the subject, by Dr. H. H. Atwater, of Vermont, who reports another case, in which he delivered the woman of a still-born child with the forceps.

The treatment of these cases presents some interest. If we see them before the waters have broken, it would be advisable to place the patient on the side in which the head is. This will make the fundus sink down on this side, and facilitate the entrance of the head into the brim and the retraction of the extremity. If this plan alone does not overcome the difficulty, we may try very cautiously to push up the leg without rupturing the membranes.

When the waters break, an attempt should immediately be made to replace the presenting extremity or extremities; but if many parts are presenting, as in the case reported above, the attempt will probably be a vain one; and if the cord is among the protruding parts, it is better not to lose any time in these vain efforts. If this is so when the vertex presents, it is, of course, still more so if the brow or the face presents. Under these circumstances turning is indicated, but there is one point I would call attention to. It is quite natural that one should first try to perform version by means of the presenting foot, but, if he does not succeed speedily, he had better try the other foot. In our case it was the right hand and foot which presented in front and to the right of the head. By drawing on the presenting leg we are liable to increase the difficulty. The fœtus becomes more and more bent to one side as the leg is drawn down, and the head does not move. By bringing down the other leg and drawing on that we make the fœtus rotate on its long axis, the extremities which are jammed together with the head in the pelvis are raised, the bent side becomes straightened out, and finally the head recedes from the pelvis. All this proved true in our case. It is only an adaptation of the rule laid down by Sir J. Y. Simpson for turning in shoulder presentations. He recommended hooking the finger behind the opposite knee. I took the foot because this part was more accessible. By acting on this principle, turning will often render all other measures unnecessary.

Dr. Landis says that to turn a dead child is to do a very useless thing, and to subject the mother to unnecessary inconvenience and risk, and he advises perforation and extraction. He does not say how, but I suppose he means with the forceps. I do not think this rule ought to be laid down without qualification. When, as in our case, the pelvis is not contracted, and the head is felt to be small, turning is a quick and easy operation, and I should think exposes the mother to less risk than perforation and forceps delivery. If, on the other hand, we have to deal with a large head or a small pelvis, I fully agree with Dr. Landis.

Dr. Atwater succeeded in delivering the woman by means of the forceps, the foot receding as he drew down the head, after he had in vain tried turning by traction on the prolapsed foot. This ought, of course, to be tried in case the child is living and turning can not be accomplished, but that will perhaps never be the case. When the child is dead, it is decidedly better for the mother to perforate the head before the forceps is applied. I would not like to turn after perforation, if it could be avoided, on account of the danger to the maternal parts arising from contact with sharp, denuded bones.*

A CASE OF STRYCHNINE POISONING IN A DOG.

By FRANK S. BILLINGS, V. S.,

BOSTON.

A very valuable pointer dog, belonging to a Mr. W., of Boston, was found in convulsions in the yard at about ten in the morning of Saturday, May 5th. The usual neighborly assistance was volunteered, but without effect. At about 4 P. M. I was called in. At that time the case looked unpromising, the animal being quite worn out, and the spasms being very frequent. The jaws were closed tetanically, so that they could scarcely be opened; the eyes were protruding; the respiration was very difficult; the extremities were cold; and the nose was dry. On the least touch, the patient went immediately into opisthotonic spasms, bending the body to the greatest possible degree, with legs stretched out and stiff. The eyes almost protruded from the sockets, and were fixed.

Diagnosticating strychnine poisoning, I gave an extremely unfavorable prognosis. The following prescription was ordered:

R Antimon. et potass. tartrat., 0·72 [gr. xij];
pulv. ipecac., 5·00 [gr. lxxv].

M. Div. in chart. No. ij.

S. One at once, and repeat in half an hour, if necessary.

The first powder not having any effect, the second was given, and a violent emesis followed. The emetic was not given with any hope of relieving the stomach of strychnine, but for the relaxing effects attributed to it, an end which was successfully attained. I think it a mistake and a waste of time to apply the stomach-pump in cases where so much time has elapsed, especially in those of strychnine poisoning, where every interference promotes spasms, and tends to the exhaustion of the patient.

The next step was to introduce atropine subcutaneously. One gramme of a solution of 0·12 to 30·00 of water was used, three injections being given in the course of an hour. Aside from this, I ordered a mustard poultice applied along the spine for half an hour, and then to be washed off as gently as possible, after which the patient was inclosed in blankets heated as warm as possible before the fire. After

* In the report of the discussion following this paper, Dr. Gillette's remarks at the time are inserted, but by an oversight my reply was left out, as well as the admission by Dr. Gillette that he was not present when the first half of the paper was read, and that he supposed it referred to a case of shoulder presentation.

the emesis was thoroughly over, two U. S. compound cathartic pills were given, which acted during the night.

I visited the patient again at 8 A. M. on Sunday morning. All appearance of spasms had disappeared, and the dog was quite intelligent, but still very weak. Ordered beef tea and light diet, and left him as cured. Up to 8 P. M. I heard nothing to the contrary.

Book Notices.

Fistula, Hemorrhoids, Painful Ulcer, Stricture, Prolapsus, and other Diseases of the Rectum: their Diagnosis and Treatment. By WILLIAM ALLINGHAM, M. D., F. R. C. S. E., etc. Fourth revised and enlarged edition, with illustrations. Philadelphia: P. Blakiston, Son & Co., 1892. Pp. 168. [Price, cloth, \$1.25; paper, 75c.]

It is customary to review "Allingham on the Rectum" by saying that the work is so favorably known that it needs no review. It is indeed favorably known, the author himself calling attention in the preface to this edition to the fact that three former large ones have been exhausted, and that it has been translated into the French, Italian, Spanish, and Russian languages. This in itself is a guarantee of the merits of a very well-known and deservedly popular work. In the present edition "an endeavor has been made to remove obscurities, correct errors, and revise generally," so that the work should be better than ever before. An index has also been added, "which, it is hoped, will facilitate reference."

Turning at once to this index, we come across the words "Pelvic fistula . . . 13," and, the subject being interesting, we turn to page 13, and find some remarks on rectal examination, but nothing about fistula. On page 17, however, we find the following: "By pelvic or rectal fistula I mean a fistula which, commencing probably by an abscess in the ischio-rectal fossa, passes underneath both the sphincter muscles and opens possibly high up in the bowel, indeed in the pelvis. This is the fistula which is dangerous to the patient, and will call forth all the knowledge and experience of the surgeon to bring to a successful issue. My friend, Dr. David Mollière, of Lyons, in his exceedingly exhaustive and able work on 'Diseases of the Rectum,' makes practically the same division, calling the first '*fistules sous-tégumentaires*,' and the second '*fistules sous-musculaires*.'" We turn back and make the correction in the index, and then, with a gratified sense of having found what we have been looking for, settle our minds to learn more about these fistulae which are dangerous to the patient, and "will call forth all the knowledge and experience of the surgeon to bring to a successful issue." A patient reading of the whole question up to the chapter on hemorrhoids, page 43, and another careful search over the index, make us no wiser than before. There is much that is useful, much that is especially valuable as stamped by the authority of the writer, but the whole question of pelvic fistulae seems to have been passed with the bare notice already quoted. Turning now to Mollière, "*Traité des maladies du rectum et de l'anus*" (not Mollière on "Diseases of the Rectum")—a work which we are inclined to believe might have been followed oftener with advantage—we find the divisions of fistula which are quoted, but we do not find that by "*fistules sous-musculaires*" he means pelvic fistulae. In fact, the term is used for the sole purpose of distinguishing an ordinary fistula, running under the sphincters, from a rather unusual variety

(*sous-tégumentaire*), which in no way implicates anything but the integument and subcutaneous tissue.

To continue this subject a little further. The author says (pp. 16, 17): "Now, these terms, 'complete,' 'blind external,' and 'blind internal,' are useful, but surgically they are of little moment; there is a very much more important division, which affects the character of the fistula as regards its seriousness to the patient, and also to the surgeon: I mean the division into anal fistula and pelvic or rectal fistula." This is new, original, and—not good. With all due deference, a rectal fistula and a pelvic fistula are not synonymous terms, nor is a pelvic fistula properly defined as one "which, commencing probably by an abscess in the ischio-rectal fossa, passes underneath both the sphincter muscles and opens possibly high up in the bowel, indeed in the pelvis"; nor does the author quite do his friend Mollière justice when he seems to make him say so. The latter very plainly (p. 22) divides the deep abscesses of this region into

"1. Those which develop above the levator-ani muscle, or abscesses of the superior pelvi-rectal space."

"2. Those which are situated less deeply, and which do not pass the limits of the ischio-rectal fossa." The fistula resulting from the former is, we believe, usually considered a pelvic fistula, while that from the latter is a rectal fistula, the *fistule sous-musculaire* of Mollière.

We leave this little question of pathology at this point and pass on to other things, only regretting that no one of the 1,208 cases of fistula, or 45 of abscess mentioned in the celebrated table of 4,000 cases, should have led the author into a few remarks which might guide the course of the general practitioner in dealing with one of those cases which "will call forth all the knowledge and experience of the surgeon to bring to a successful issue."

In the chapter on hemorrhoids there is little to criticise. The author does not believe in the treatment by injections of carbolic acid or of anything else, but his objections read rather curiously. "It appears to me," he says, "that all attempts to destroy vascular growths by causing coagulation of blood or inflammation in them, while they are not shut off from the general circulation, must be fraught with danger. You can have no guarantee that the coagulum may not break down, and minute particles of dead tissue find their way into the vascular or lymphatic systems, and result in embolism, or pyæmia, or both." This strikes us as pre-eminently true, but we wonder at the same time whether the injection of one drop of water, one of glycerin, and one of carbolic acid (the formula he mentions), is any more likely to cause embolism, or pyæmia, or both, than the application of half a dozen ligatures and the excision of the tumors. How, we wonder, would the author deal with a nevus of the scalp in a young child? Would he attempt to cause the coagulation of blood or inflammation in it in spite of the danger which might attend its not being cut off from the general circulation; or would he be deterred by the fear of embolism, or pyæmia, or both? Or is the coagulum formed on the proximal side of a ligature, which has been thrown around the base of a vascular tumor, any more shut off from the general circulation than one which is caused by the injection of an irritating fluid into the tumor? Whatever the answer may be, American quacks will go on curing their patients by injections, and the treatment will be accepted or rejected by the general practitioner according to its results, and not according to any preconceived theoretical objections.

There is one thing that has always struck us with surprise in reading Allingham's report of his own operation, and that is how much better results he gets from it than other men do. Of course, this is but natural, and the remark has absolutely no

hidden meaning, and contains no innuendo. But it is a well-known fact that, in America at least, Allingham's operation is not the harmless, simple thing his own figures show. He has operated 1,600 times without a single fatal result. No such percentage obtains here. But, excluding a fatal result, the operation is attended by pain, hemorrhage, sometimes by grave symptoms of constitutional disturbance, and not unfrequently by subsequent contraction of the bowel to a point which demands treatment by dilatation. The young practitioner is apt to imagine that this particular operation is considerably more trifling as far as unpleasant consequences go than opening a boil, and invariably assures his patient, on the authority of the author, that there will be no danger, and only trifling pain. The older surgeon does not undertake it without considerable doubt in his own mind as to the amount of trouble he and his patient are to have before the wounds are healed.

Under the head of *Procidencia Recti* (p. 88) we find the following: "I have had, in my own practice, many cases of procidencia in which there was a hernial sac in the protrusion, and in all it was situated anteriorly, as, from the anatomy of the part, of course, it must be." On this subject also we can not but wish the author had been more explicit, for the subject of rectal hernia is an important one, the cases are rare, and any one who has seen many of them owes more to the profession than we got from this book. However, we will only ask why, from the anatomy of the parts, the hernia must, of course, be in the anterior portion of the prolapse, when some very reliable observers have reported cases in which, in spite of the anatomy, it was in the posterior?

On page 96, fourth prescription, there is a printer's error which would trouble an American practitioner who wished to use the formula. The word "(Wright's)" applies to the liq. carbonis detergens, an English secret preparation of coal-tar, and not to the glycerin, as written.

We have said enough to indicate what we believe to be the just and fair criticism of this well-known book. It is one which derives its great value from the authority of the writer more than from the amount of work he has expended upon the book itself. What he says must have weight because he says it, but how much more he might have said! how much more might have been culled by other hands from the same bountiful supply of opportunity! As it is, we have the same Allingham (in the fourth edition much the same as in the other)—practical, safe, full of valuable experience and suggestions, but unsatisfactory in its incompleteness, and in the noticeable omission of almost all that is not a record of the simplest every-day practice of one who has devoted himself to the treatment of these cases. The late Dr. Van Buren had not, perhaps, as large an experience as Allingham, but his book on the same subject shows far more thought, scholarship, and work, and is, for this reason, a better one.

The International Encyclopedia of Surgery. A Systematic Treatise on the Theory and Practice of Surgery. By authors of various nations. Edited by JOHN ASHBURST, JR., M. D., Professor of Clinical Surgery in the University of Pennsylvania. Illustrated by chromo-lithographs and woodcuts. In six volumes. Vol. II. New York: William Wood & Co., 1882. Pp. xl-754.

In the second volume of this important work the following subjects are treated by the following authors: Contusions, by Dr. Hunter McGuire; Wounds, by Mr. Bryant; The Antiseptic Method of Treating Wounds, by Mr. Cheyne; Poisoned Wounds, by Dr. Packard; Saber and Bayonet Wounds, Arrow Wounds, by Dr. J. H. Bill; Gunshot Wounds, by Dr. P. S. Conner; The Effects of Heat, by Dr. T. G. Morton; The Effects of Cold, by

Dr. J. A. Grant; Abscesses, by Mr. Howard Marsh; Ulcers, by the late Dr. Hodgson; Gangrene and Gangrenous Diseases, by Dr. E. M. Moore; Gonorrhoea, by Dr. J. W. White; The Simple Venereal Ulcer or Chancroid, by Dr. F. R. Sturgis; Syphilis, by Dr. Van Harlingen; Eruptions of Eczema, Venereal Warts or Vegetations, Pseudo-Venereal Affections, Venereal Diseases in the Lower Animals, by Dr. H. R. Wharton; Surgical Diseases of the Skin and its Appendages, by Dr. J. C. White; Diseases of the Cellular Tissue, by Dr. J. W. Howe; and Injuries and Diseases of the Bursae, by Dr. C. B. Nancrede. It will be noticed that of the eighteen writers all but three—Bryant, Cheyne, and Marsh—are Americans.

The chapter on contusions is short, but practical and valuable, especially the part which relates to the treatment of extravasations of blood, the puncturing of ecchymoses, etc. The chapter on wounds covers most of the important points connected with them, such as their classification, the process of repair, and their treatment. Special attention is given to treatment by water-dressings both with and without antiseptics in solution, and to the open method of treatment. The question of antiseptic treatment proper is considered by Mr. Cheyne in the third chapter, who goes over both the practical details of the treatment and the theory upon which it is based. The article on poisoned wounds contains much more information on the subject than is often to be found in any one place. It deals with dissecting wounds first, and with analogous diseases, such as animal typhus and wool-sorter's disease, and after this with the bites of the various poisonous insects and the snakes, dealing with each in a few words, but giving much valuable information.

The next hundred pages are devoted to saber and bayonet wounds, arrow and gunshot wounds. The two former varieties are disposed of in few words, the one being simply an incised wound, and the other very rare, for the reason that the bayonet is seldom in actual use by the soldier. The chapter on arrow wounds is very complete and full of interest, the material for it being drawn from the frequent difficulties which our Government has with the Indians. The gunshot wounds are first considered in a general way, and then the wounds of each particular part of the body are individually described with the proper means of treatment, the chapter as a whole being a very complete *résumé* of what is known and generally accepted as to this branch of military surgery. The chapter on the effects of heat includes burns and scalds, sunburns, burns from caustics, and lightning strokes, with the treatment of each and of the resulting deformity. The effects of cold are arranged under the two heads of chilblain or pernio, and frost-bite, the latter including the severe cases where large portions of the body are frozen. The question of abscesses is considered by Mr. Marsh as far as possible independently of the question of inflammation, which purely artificial division of the subject has rendered his task a difficult one. He considers, however, at first, the characters and properties of pus, and then the practical points in connection with abscesses, their divisions, symptoms, complications, and treatment, the chapter being rather practical than pathological. After this come the chapters on ulcers and on gangrene, the latter by Dr. Moore, of Rochester, being one of the best in the book, and including carbuncle, noma, and boil.

The following chapters, covering nearly three hundred pages, are devoted to venereal diseases. Gonorrhoea, with all its complications, in the male and female, is first thoroughly considered by Dr. White, then the chancroid by Dr. Sturgis, and finally syphilis by Dr. Van Harlingen, the whole making a complete work on this subject. Finally, we have chapters on the skin, the cellular tissue, and the bursae, the latter closing the present volume.

As a whole, the work fulfills the promise given by the volume which preceded it, and is one of practical value, apparently designed as a book of reference for the practitioner. This purpose it answers admirably, for the most valuable part of the book is the practical part—the hints as to diagnosis and the suggestions as to treatment. The reader is at once led to a comparison of its merits with the similar work by Holmes, and the comparison is not to the detriment of the one under consideration.

Nerve-Vibration and Excitation as Agents in the Treatment of Functional Disorder and Organic Disease. By J. MORTIMER GRANVILLE, M. D. London: J. & A. Churchill, 1883. Pp. 128.

THE theory that general and special sensibility are the results of vibrations of the ultimate particles of the nerves, and that nerve-force of all kinds has a like origin, are theories that were first propounded by Sir Isaac Newton, and subsequently greatly elaborated by David Hartley. As the latter says: *

"These vibrations are motions backward and forward of the small particles; of the same kind with the oscillations of pendulums and the tremblings of the particles of sounding bodies. They must be conceived to be exceedingly short and small, so as not to have the least efficacy to disturb or move the whole bodies of the nerves or brain. For that the nerves themselves should vibrate like musical strings is highly absurd; nor was it ever asserted by Sir Isaac Newton, or any of those who have embraced his notion of the performance of sensation and motion by means of vibrations."

We do not, however, find anywhere in Dr. Granville's book any acknowledgment of his indebtedness to Hartley; on the contrary, we are led to the idea that the whole theory of the physiological and therapeutical actions of vibrations is one which, till Dr. Granville's views were published, had not entered into the mind of man. To be sure, we are treated to an elaborate refutation of the claims of M. Boudet, of Paris, who seems, somehow, to have made the first publication of the value of vibration as a therapeutical measure, although Dr. Granville had before him made use of the principle in his practice. But surely Dr. Granville should have said something about Hartley before demolishing M. Boudet. Thus, he says:

"I do not affirm that nervous force is the product of nerve-vibration, but science certainly justifies the belief that nerve-action or activity consists in, or is accompanied by, vibrations of the essential elements of nervous tissue in the body or frame—so to say—formed by the complementary parts of its structure.

"Cells vibrate as bodies in the intercellular stroma of the gray matter, and fibers vibrate as delicately poised rods or strong cords within the partite cylinders formed by internal prolongations of the neurilemma or nerve-sheath."

This is Hartley's doctrine, pure and simple.

The application of the theory to therapeutics is fairly Dr. Granville's idea. If certain diseases of the nervous system are the result of a series of morbid vibrations, it is reasonable to suppose that they may be cured by setting up a new series of vibrations not morbid; and this is done by percussion, more or less frequently repeated, as the circumstances seem to require. For effecting the object in view, *percutors* are employed. These are instruments worked by clock-work, or by electricity, by means of which blows are given, with suitable hammers, over the parts which it is thought necessary to subject to treatment. If, for instance, the case be one of neuralgia, percussion is made over the seat of the pain as nearly as possible to the nerve—rapidly if the pain be dull and aching, slowly if it be

acute and lancinating. For the details, reference must be made to Dr. Granville's book. We may state, however, that in some cases in which we have used the principle in question it has appeared to do good, and that it is especially useful in that affection to which the term "spinal irritation" is applied. For this, it suffices to percuss the painful regions with two of the India-rubber rattles used for the amusement of infants, for about five minutes, night and morning.

Brain Rest. By J. LEONARD CORNING, M. D., formerly Clinical Assistant to the Manhattan Eye and Ear Hospital, etc. New York: G. P. Putnam's Sons, 1883. Pp. 103. [Price, \$1.]

WE fain would praise and welcome this *brochure*, for the author's zeal and good faith are clearly discernible in its pages; but, in spite of a leaning amiability, we are quite unable to see for it a valid *raison d'être*. If it be needful to insist, with wearisome reiteration, upon the acceptance of unquestioned physiological facts, and principles which are almost axiomatic in their self-evident truthfulness, then the work is a warrantable effort, but not otherwise.

"It is very necessary to have some conception of the normal before proceeding to investigate the nature of abnormal phenomena." Hence, the first chapter is devoted to an exposition of the physiology of sleep. With a slight change in the side-dishes, the same meat is served again under the new name of Blood and Brain-Force, for the refutation of the second chapter. Following we have consistently treated the Hygienics of Sleep, Definition of Insomnia, and Therapeutics.

The author deems it worth while to vindicate, and returns more than once to the attack, a proposition asserting the dependence of mental phenomena upon cerebral blood-supply. Is it possible to find any one—deserving of one's ammunition—who would deny this dependence?

To say that these 103 pages do not contain any serious error is, we fear, to condemn with faint commendation. Much that would be acceptable might be reclaimed from existing knowledge within the ground covered by the title of this little book. But Dr. Corning's incubation will not receive the cordial reception of a profession much overwrought by a general *cacoethes scribendi* until, at least, it has been shorn of its sentiment and its platitudes, wound up as to the thread of its verbosity, and strengthened in the staple of its argument.

Lectures on Orthopaedic Surgery and Diseases of the Joints. Delivered at Bellevue Hospital Medical College, during the winter session of 1874-75. By LEWIS A. SAYRE, M. D., Professor of Orthopaedic Surgery and Clinical Surgery, etc. Second edition, revised and greatly enlarged. With 324 Illustrations. New York: D. Appleton & Co., 1883. Pp. xx-569.

ALTHOUGH still entitled a book of lectures, the new edition of Dr. Sayre's work is so much more systematic in its arrangement than the first that it may fairly be called a text-book. But, with all the evidence it bears of careful revision, not only in regard to the rearrangement of its parts, but in other respects as well, it still retains the charm that marked it before—that it is essentially a reflection of the author's personal study and achievements, and in no sense a mere putting together of other men's work. It must be said, nevertheless, that Dr. Sayre is so frank and manly in the matter of according full credit to his contemporaries that the reader can not but feel that it is to him a pleasure, rather than a forced concession, to speak of them in terms of generous praise.

There is no radical change in the doctrines enunciated or

* "Observations on Man," etc., London, 1791, p. 4.

the practice inculcated, but a wider range is covered than in the first edition, and the maturer experience and judgment of the author are drawn upon. Heartily as the original work was welcomed, the present edition can scarcely fail to meet with still greater favor.

On the Pathology of Bronchitis, Catarrhal Pneumonia, Tubercle, and Allied Lesions of the Human Lung. By D. J. HAMILTON, M. B., F. R. C. S. E., F. R. S. E., Professor of Pathological Anatomy (Sir Erasmus Wilson Chair) University of Aberdeen. With illustrations. London: Macmillan & Co., 1888. Pp. xii-248. [Price, \$2.50.]

This work had its origin in a series of papers which appeared in the "Practitioner" for the years 1879 and 1880. Since then revisions and alterations have been made wherever modern research has called for them. The author has attempted to make clear the subject of tubercle and phthisis, and the relations of both these to bronchial affections. He inclines a little to the doctrine of Virchow and Niemeyer, that tubercle may be developed from the caseous degeneration of substances not originally tuberculous. He admits that tuberculosis is contagious, but believes that contagion is a very rare cause of phthisis in the human subject. The illustrations are well printed, and in many cases very striking. The author bases his conclusions upon careful research, and supports them with a confidence expressive of strong convictions.

Early Aid in Injuries and Accidents. By Dr. FRIEDRICH EMMERICH, Professor of Surgery at the University of Kiel, etc. Translated from the German by H. R. H. Princess Christian. Philadelphia: Henry C. Lea's Son & Co., 1883. Pp. viii-17 to 117, inclusive.

The author says: "When I look back on my career as a surgeon, I can with truth say that many and many are the times I have deplored that so very few people know how to render the first aid to those who have suddenly met with some injury. . . . How many there are every year who die a miserable death, and who might have been saved by prompt aid, had any one been near who knew how to give it." For this reason a great surgeon has written this little book, full of the simplest things in anatomy and surgery—a book which would serve an excellent purpose as a text-book in every school and college in the land, and which contains a great deal which goes to make up the daily practice of the active practitioner. The public would probably be surprised if they knew how much of the daily practice of medicine and surgery is contained in these 117 pages.

A Compend of Obstetrics. Especially adapted to the use of Medical Students and Physicians. By HENRY G. LANDIS, A. M., M. D., Professor of Obstetrics and Diseases of Women in Starling Medical College, etc. With illustrations. Philadelphia: P. Blakiston. Son & Co., 1883. Pp. 107. [Quiz Compend, No. 5.]

SOME months ago we had occasion to notice Dr. Landis's excellent monograph on the obstetric forceps, the originality and logical character of which led us to welcome him as a new and important contributor to obstetrical literature. We regret that we can not bestow the same praise on this little book of questions and answers. We can only say that it is a good one of its kind, but that the kind is exceedingly poor.

A Manual of Auscultation and Percussion; embracing the Physical Diagnosis of Diseases of the Lungs and Heart, and of Thoracic Aneurysm. By AUSTIN FLINT, M. D., Professor of the Principles and Practice of Medicine and of Clinical

Medicine in the Bellevue Hospital Medical College, etc. Third edition, revised. Philadelphia: Henry C. Lea's Son & Co., 1883. Pp. 242.

This little work is well known, and its popularity is attested by the rapidity with which the second edition has been exhausted. It is sufficient to say that the present edition has been revised wherever more recent investigations have cast new light upon the subject.

The Treatment of Acute Rheumatism: an Analysis of the Results obtained under Different Systems of Treatment in St. George's Hospital during the years 1877 and 1878. By ISAMBARD OWEN, M. D., Lecturer on Materia Medica and Therapeutics, and late Medical Registrar of St. George's Hospital. London: J. & A. Churchill, 1883. Pp. 28.

THE treatment of rheumatism has received such elaborate discussion and investigation at the hands of English physicians that a work with the foregoing title must be of interest to all practicing physicians. The cases are carefully analyzed and the results tabulated.

BOOKS AND PAMPHLETS RECEIVED.

A Treatise on Therapeutics, comprising Materia Medica and Toxicology, with Especial Reference to the Application of the Physiological Action of Drugs to Clinical Medicine. By H. C. WOOD, M. D., Professor of Materia Medica and Therapeutics, and Clinical Professor of Diseases of the Nervous System, in the University of Pennsylvania, etc. Fifth edition, revised and enlarged. Philadelphia: J. B. Lippincott & Co., 1883. Pp. xiii-17 to 740, inclusive. [Price, \$6.]

A Practical Treatise on Impotence, Sterility, and Allied Disorders of the Male Sexual Organs. By Samuel W. GROSS, A. M., M. D., Professor of the Principles of Surgery and Clinical Surgery in the Jefferson Medical College of Philadelphia, etc. Second edition, thoroughly revised. With sixteen illustrations. Philadelphia: Henry C. Lea's Son & Co., 1883. Pp. viii-17 to 176, inclusive.

Facts regarding the Medical Profession and Sanitary Science, etc. By Carl H. HORSCH. Dover, N. H., 1883. Pp. 18.

How Can We Obtain and Preserve the Best Eyesight and Hearing? By LEARTUS CONNOR, A. M., M. D., Detroit. [Reprint from the "Annual Report of the Michigan State Board of Health."]

A Clinical Study of Syphilis of the Eye and its Appendages. By LEARTUS CONNOR, A. M., M. D., Detroit. [Reprint from the "American Journal of the Medical Sciences."]

Algas Termales. Descripcion Micrográfica de Algunas Especies Presentadas en la Exposicion de Minería, Aguas Minerales, etc. Por Eduardo Moreno, Medico-Director, por Oposicion, de Aguas Minerales. Madrid, 1883. Pp. 44.

Handbook of Medical Electricity. By A. M. ROSEBRUGH, M. D., Surgeon to the Toronto Eye and Ear Dispensary, etc. Toronto, 1883. Pp. 54.

MEDICAL MEN AS WITNESSES.—The "British Medical Journal" reminds its readers that one of the Scottish judges some months ago expressed an opinion regarding medical evidence in the witness-box which was far from flattering to the profession, or possibly far from just to it. The journal in question adds, however, that a pleasant sort of reparation has recently been made by the same judge, Lord Deas (one of the most venerable on the Scottish Bench), in a harder case recently tried before him in Glasgow. He complimented one of the medical witnesses (Dr. James Wallace, of Greenock) on the cautious and intelligent evidence given by him in this case, in which the trial was of two men for murdering two gamblers, and in which conviction was secured and sentence of death passed on both.

FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, JUNE 16, 1883.

THE RECENT MEETING OF THE AMERICAN MEDICAL
ASSOCIATION.

WE lately remarked that the meeting at Cleveland would probably be a large one, and so it turned out to be. It is said, indeed, to have been the largest ever held, with the single exception of the New York meeting three years ago. The attractiveness of the city in which the meeting was held doubtless accounts in great measure for the large attendance. The chance that an ethical discussion would arise may have counted for something among the younger men, but those who were familiar with the methods of the association must have been aware that any positive action affecting the code, or even any real discussion of the subject in open session, could scarcely fail to be postponed to next year.

Still, there was a general feeling among a large number of the members of the profession in this State who had allowed their names to be used as discountenancing any alteration of the code by other organizations than the American Medical Association, although many of them thought a change advisable, that the representations made to them to induce them to allow of such use of their names warranted the expectation that the question of a revision of the code would be brought before the meeting by the leaders of the old-code party in New York. As we said on a former occasion, we believe they were perfectly justified in the expectation alluded to, and we can not see how a sense of having been cajoled can fail to be mingled with their disappointment.

It must have been somewhat of a surprise to those in attendance who favored a revision of the code to find that the only suggestion of such a course that came before the meeting was in the form of a communication from a society in St. Louis. To us, this is but another of the many facts pointing to the existence of a widespread feeling of dissatisfaction with the code as it stands. Indeed, it seems as if the gentlemen who control the American Medical Association must have had a very decided inking of the state of things; otherwise they would hardly have thought it necessary to gag the meeting by refusing seats to all who would not sign in advance a pledge to support the code as it is.

Some of the members demurred to this pledge, but signed it under protest. They could do nothing more; they had to sign or be turned away without redress. This is one of the beautiful results of consenting to be controlled by an organization that has no existence in the eyes of the law, and, therefore, has not the constitutional right to be sued. The simple fact is, that the American Medical Association can deal as it pleases with individuals, and, so long as it does not invade their rights

as citizens, it can not be called to account. The worst feature of all is, that not only can the general meeting do this, but the Judicial Council can do the same, as it did in this instance.

The length to which this violation of individual rights may be carried is strikingly shown in the case of Dr. Goodwillie, of this city, who, having signed the pledge under protest, as we understand, and been registered, was not allowed to read the address he had prepared as chairman of a section, and was at last virtually kicked out of the meeting, his registration being canceled, and his annual dues being returned to him. We are not told that Dr. Goodwillie had committed any overt act that met the disapproval of the meeting, or even that of the Judicial Council. The only inference we can draw from the affair is, that the association is determined that none of its members shall dare to think any of its doings unwise, or, at all events, shall not venture to give expression to such a thought.

We have no fault to find with the members of the Judicial Council as men. For most of them we have the greatest respect. We are quite willing to believe that they are guided by what they take to be considerations looking to the welfare of the profession; whether or not they are mistaken, time will show. The history of the world bristles with iniquities perpetrated *ad majorem dei gloriam*. Power should always be coupled with responsibility. "We take the responsibility," said Dr. Davis, speaking in behalf of the Judicial Council in the matter of the pledge extorted from every participant in the meeting; yet all who heard his voice must have known that the words were but empty sound. A man responsible to himself is not responsible to all; and the same is true of organizations. It may, indeed, be possible for the association at large to call the Judicial Council to account, but even that involves but a shifting of the semblance of responsibility, for who shall arraign the association itself? Is it to be wondered at that the Medical Society of the State of New York, having drawn its head out of the grasp of this oligarchy, declines to sue for that peace which is exemplified by the lion and the lamb lying down together—the lamb inside the lion? New York desires peace, but for the "peace at any price" policy she has no stomach.

THE QUESTION OF A STATE EXAMINING BOARD.

THERE is little if any diversity of feeling among the progressive and thinking portion of the profession, whether in this State or elsewhere through the country, on the broad question of the desirability of a change in our methods of granting licenses to practice. But how best to effect that change is a problem. If we had to take into account only our leading colleges, there would be no ground for the sentiment to which we refer, for every one in a position to judge of the matter knows that those institutions have constantly been raising their standards, especially within the last twenty years. It is a subject of general congratulation, and one in regard to which the colleges may well be proud, that, unaided and unrestricted by the State or by any corporate authority beyond their own, they have extended their courses, increased the amount of actual work required of students, and in every way made their diplomas

harder and harder to obtain. All this they have done, as we have before pointed out, in obedience to business principles, and we have not the slightest doubt that they will continue in the same course in the future if left to themselves. They are as far above the necessity of competing with the inferior colleges as a great banking house is above feeling the rivalry of a pawnbroker's shop.

Unfortunately, however, the profession at large and the community are not so independent. Any so-called college, no matter how absurd its pretensions may be as an institution of learning, may spew forth its "graduates" without let or hindrance, provided only it has succeeded in getting an act of incorporation, and it must be poor indeed in devices not to have been able to accomplish that much. He whom it invests with its degree, whether on account of a certain grade of proficiency in medical study, by reason of favoritism, or, to use no harsher term, as an expression of its good nature, is equal before the law with him who has toiled long and hard to achieve a status that is legally not a whit better. The two are on the same footing before the community at the start, and the community is slow to make subsequent distinctions in such matters. Not only is a material injury thus wrought to the painstaking members of the profession, and indirectly to the public, but the esteem in which medicine is held suffers likewise. People do not judge doctors as a class by the brightest of their number, but by the average qualities they seem to show. Let any one of the vast herd of scamps and incompetents that are decked with the degree of doctor in medicine incur reprobation, and discredit results to the profession as a whole.

It is not for the sake of the great colleges, therefore, that a change is desirable, although a commendable change could scarcely prove to their disadvantage, and might be of profit to them. It is the demand of the decent part of the profession that they shall not for ever be classed in the same category with pretenders; and to acquiescence in this demand, and even to its advocacy, must the general public come in the end, including, let us hope, the men who make laws. As we said at the outset, however, the precise form in which that demand can best be enforced is not easy to determine. On a subsequent occasion we shall mention some of the considerations which we think should have a bearing upon the settlement of the question.

INADEQUATE MEASURES AGAINST INFECTIOUS DISEASES.

THE "Cincinnati Lancet and Clinic," commenting upon the course pursued by the sanitary officials of Cincinnati in the matter of a music-school in which, as we lately informed our readers, one of the pupils had fallen a victim to small-pox, says: "The health officer quarantined the house after the damage had been done. This simply serves to frighten the nervous, and to cause the people to depend on the quarantine for protection against the disease. Our health officer ought to know that small pox could not be quarantined. That never has sufficed to check the spread of the disease, and it never will suffice. Vaccination is the only protection against small-pox. The sooner that lesson is taught the people and the profession, the sooner

will the scourge cease. All other methods of controlling it only divert the minds of the people from the right way."

Our contemporary's forcible expressions are abundantly justified, and such injunctions, coming from authoritative sources, are needed not only in Cincinnati, but in every community. Were it the people alone that required to be set right in the matter, the task would be comparatively easy. As it is, their mistaken notions are bolstered up every now and then by implications that this or that outbreak of small-pox is caused, or, intensified, or spread by filth. We would be the last to hamper sanitary boards in their endeavors to impress upon the public the necessity of cleanliness as a measure in the highest degree conducive to public health, but we can not admit that good is likely to result in the long run from official utterances that imply, even if they do not assert, such a connection between mere filth and the prevalence of the disease in question. It is legitimate, of course, to regard refuse of all sorts as including many possible vehicles of the contagium, but the deductions drawn by the community from such statements as we allude to do not stop at that; to a very great extent the public have imbibed the notion that filth is *per se* capable of generating the disease.

Another erroneous notion—one, too, that we fear boards of health are to a certain degree answerable for, from their tendency to underrate the magnitude of outbreaks of contagious disease, and to push a laudable purpose of encouraging those who look to them for advice to the length of intimating that timidity is uncalled for—is, that it is chiefly those who are overcome with fear that contract pestilential diseases. No doubt the depression of the system that results from morbid apprehension adds to the gravity of the attack in individual instances, but the absurdity of accounting dread as actually an exciting cause of the outbreak would be obvious to any one were he reminded of the simple fact that infants, to whom fear from such a cause is unknown, suffer to the full extent from small-pox and other like diseases.

THE OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION.

THE association has usually been fortunate in its pre-idents, and this year has proved no exception to the rule. Though past eighty years of age, the outgoing president, Dr. Atlee, evidently took a great deal of pains to so shape his introductory address that it should indeed strike his hearers as the words of "an oldest brother," as he expressed it. The mere presence of such a man, whether in the chair or among the benches, is always a source of strength to a deliberative assembly, and we may well conceive that Dr. Atlee's occupancy of the chair was a matter of congratulation to the meeting.

In its newly elected president, also, the association has done itself an honor. Dr. Flint's position has been such for years that no distinction in the power of the profession to confer upon him could heighten it. It is to be hoped that the meeting over which he will be called to preside at Washington next year will be of such a character as to tempt him for a few years he will undoubtedly take to make it worthy of the profession.

We should be glad to be able to speak in like terms of the officials of the association as a whole, but the utmost strain of optimism can scarcely look upon them as other than mediocre, with a few exceptions. The chairmen of the sections ought to be men of unquestioned eminence in the several branches to which the sections are devoted. With regard to most of them, however, such is not the case. It seems important, too, that those who are deputed to represent the association abroad should be men whose passports are to be found in the form of a world-wide repute. In point of fact, almost any member who was able to say at the recent meeting that he intended to go to Europe during the summer found no difficulty in getting himself appointed a delegate.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

THE association is now fully committed to the experiment of publishing a weekly journal, and it is announced that the appearance of the first number may be looked for early in July. It is to be edited by Dr. N. S. Davis, of Chicago, and published in that city. Dr. Davis is not new to the work, and he knows, therefore, what an undertaking he has consented to assume. There is everything to indicate that he does it for the good of the enterprise, and not because it could in any way conduce to his personal advantage. We wish him all manner of success with the journal, and we look forward to its appearance with pleasant anticipations.

THE POWER OF HEALTH BOARDS TO ABATE NUISANCES.

THE powers possessed by boards of health in cities to prevent the continuance of nuisances is a matter of public importance, and the courts have in general been careful to protect them in the exercise of their duties. In a case that lately came up in Buffalo, an injunction obtained by the owner of cattle against the Board of Health, which had directed their removal as a "sanitary necessity," was dissolved upon appeal, and the board's action was approved. The principle involved was somewhat as in a recent English case, where a property owner obtained an injunction against the use of neighboring premises for a small-pox hospital. In this case, as we have already informed our readers, the suit was dismissed on technical grounds, but the judge intimated very strongly that, had the papers been regular, the injunction would have been continued on the ground of danger to the public health.

THE BILL TO RESUSCITATE THE UNITED STATES MEDICAL COLLEGE.

GOVERNOR CLEVELAND has declined to sign the bill legalizing the organization and the acts of the United States Medical College, as well as the degrees conferred by it, to which frequent reference has been made in these columns, and it therefore fails of becoming a law. This action of the Governor was expected, as the bill would, had it become a law, have been a palpable interference with the decisions of the courts, and it was, moreover, so broad in its provisions as to cover doings of the college not now known, but which might hereafter be shown to be injurious to the public welfare. The question as to the validity of the organization of the college will now be thoroughly examined by the courts. The last phase of the litigation has been the appeal to the General Term of the Supreme Court, from the

decision of the trial court, which was adverse to the college. Argument was heard on the appeal a short time since, but a decision has not yet been rendered by the General Term.

MISTAKES IN FILLING PRESCRIPTIONS.

THE newspapers contain frequent accounts of mistakes made by apothecaries in preparing medicines prescribed, some of which turn out to be very serious.

In a recent case tried in the Marine Court of this city a verdict of \$100 was rendered against an apothecary on Second Avenue for negligence of this kind. The plaintiff testified that a single dose of the medicine as prepared made her so ill as to confine her to her bed for a month. The defendant admitted a mistake in the preparation, but contended that the compound ought not to have produced the ill effects complained of. The jury regarded the mistake as a serious one, and gave a verdict for the woman.

Proceedings of Societies.

AMERICAN MEDICAL ASSOCIATION.

Wednesday, June 6th—Second Day.

(Concluded from page 642.)

THE COMMITTEE ON NOMINATIONS.*—The session having been opened with a prayer by the Rev. Charles S. Pomeroy, D. D., the secretary announced the names of the Nominating Committee as follows: Drs. W. O. Baldwin, Alabama; D. A. Linthicum, Arkansas; W. F. McNutt, California; T. M. Hills, Connecticut; H. K. Steele, Colorado; W. Marshall, Delaware; D. C. Patterson, District of Columbia; Eugene Foster, Georgia; C. F. Parker, Illinois; H. J. Wood, Indiana; W. S. Robertson, Iowa; L. S. McMurtry, Kentucky; W. L. Schenck, Kansas; J. W. Dupree, Louisiana; C. A. Savory, Massachusetts; Julian J. Chisolm, Maryland; B. H. Miller, Minnesota; F. K. Owen, Michigan; E. H. Gregory, Missouri; A. J. Fuller, Maine; V. H. Coffman, Nebraska; E. Grissom, North Carolina; B. A. Watson, New Jersey; H. D. Didama, New York; W. M. Beach, Ohio; S. D. Gross, Pennsylvania; A. Ballou, Rhode Island; R. A. Kinlock, South Carolina; D. J. Roberts, Tennessee; H. C. Ghent, Texas; Alexander Harris, Virginia; J. M. Lasell, West Virginia; S. C. Johnson, Wisconsin; T. W. Miller, United States Marine-Hospital Service; Joseph R. Smith, United States Army; A. L. Gihon, United States Navy; W. A. Tipton, New Mexico; A. B. Van Nelson, Dakota Territory.

A NEW BY-LAW.—Dr. FOSTER PRATT, of Michigan, moved to take from the table a proposition, made at St. Paul last year, to amend the by-laws of the association. The motion was carried. Dr. Pratt then moved the adoption of the following amendment:

"That section 13 of the by-laws be and it is hereby amended so as to read as follows: That none but members present shall be elected president, vice-presidents, secretary, or treasurer of the association, or chairmen or secretaries of sections." Carried.

The new by-law leaves to the Nominating Committee discretionary power with regard to the minor officers.

THE ARMY MEDICAL MUSEUM AND LIBRARY.—Dr. SAMUEL D. GROSS presented a paper, signed by himself, Austin Flint, Sr., and Oliver Wendell Holmes, praying Congress to make an appropriation for the National Public Museum and Medical Li-

* A partial list of the members of the committee was published in our report of the first day's proceedings.

brary, now located at Washington, in order to preserve the valuable collection from danger by fire. This communication was referred to the publication committee.

Dr. H. A. JOHNSON, of Washington, presented the following resolutions:

Whereas, There has been formed in Washington, under the direction of the medical department of the army, a museum of unrivaled completeness and excellence, illustrating military medicine and surgery, and a medical library which is believed to be the largest and most valuable in the world; and

Whereas, It is believed to be of the highest importance for the promotion of medical science, literature, and education in this country, that these collections should be preserved and made and kept as complete as possible; and

Whereas, It is believed that this can be best done by keeping them together under the management which has already produced such excellent results, and by its publications has made them available for use throughout the country. Therefore,

Resolved, I. That the American Medical Association respectfully urges upon Congress the importance of at once providing a commodious fire-proof building to contain the Army Medical Museum and Library.

II. That the annual appropriation for this library should be sufficient to enable it to obtain all new medical publications of all countries as soon as they appear, and also to complete its collection of medical books heretofore published; and that for this purpose the sum of ten thousand dollars is considered a reasonable and proper annual appropriation, and Congress is requested to grant that sum in addition to the amount required for the Medical Museum.

III. That it is of the greatest importance that the "Index-Catalogue" of this library, now in the course of publication, should be issued as rapidly as it can be properly prepared for the press, and Congress is urged to make the necessary appropriations for this purpose.

IV. That a special committee of five be appointed, of which the president of the association shall be *ex-officio* chairman, to present this matter to Congress and to call the attention of State and local medical societies, and of all who are interested in the progress of medicine, to the importance of furnishing to members of Congress and Senators full information as to the value of this museum and library, and the esteem in which they are held by the medical profession of the United States. The resolutions were adopted.

THE PROPOSED JOURNAL OF THE ASSOCIATION.—At the conclusion of the reading of Dr. Johnson's resolutions the Report of the Board of Trustees was read by N. S. DAVIS, M. D., Chairman, on the subject of journalizing the transactions. Dr. Davis stated that each member of the board had signed the report after due consideration, and asked for its favorable consideration by the association.

The following is a synopsis of the Report of the Board of Trustees concerning the feasibility of publishing a weekly medical journal instead of an annual volume of transactions:

Resolved, That the interests of the association would be promoted by the publication of its transactions in a weekly medical journal under its own control, instead of in an annual volume, as heretofore, provided it could be done without involving pecuniary embarrassment, or so far encroaching its funds as to prevent the annual encouragement of original investigations by its members.

[The name recommended was, "The Journal of the American Medical Association."]

Resolved, That the Board of Trustees retain entire control of the medical journal.

Also *Resolved*, That the treasurer of the association pay the

necessary expenses of the Board of Trustees in printing, distributing of circulars, and correspondence.

In accordance with the foregoing resolutions, which were adopted at St. Paul in 1882, a board of trustees was appointed. After the adjournment of the association, a meeting of the board was held, and an organization was effected. The board agreed upon a plan of a journal, and issued 40,000 circulars and blank pledges of support of such journal, which were sent to the members of the profession throughout the country; 2,150 answers were returned, of which only twelve were direct expressions of opposition to the proposed change in the mode of publication. After a careful analysis and comparison of the returns containing pledges, the members of the board voted unanimously in favor of recommending the publication of the journal as previously proposed, being satisfied that it could be done without embarrassment to the association.

Having decided this question, the board proceeded to consider the general plan on which the work could be most efficiently conducted, and the most favorable place for its publication, which resulted in the adoption of the following propositions:

1. The editor to have direct supervision of the whole work, and for business purposes he should employ a clerk, also an assistant editor, or assistants specially qualified in all departments of medical science.

Also to establish a direct correspondence with the proper officers of the State societies.

All advertisements of proprietary or patent medicines to be excluded. Also any advertisement having the name of any member of the profession as indorser. In other words, no advertisements should be admitted which contravene in letter or spirit the principles of the national code of ethics.

It is thus seen that the Board of Trustees has endeavored to promptly and faithfully comply with the instructions given and execute the work enjoined upon it in the resolutions adopted by the association, at its annual meeting in St. Paul, June, 1882—

1. By agreeing upon a plan for the proposed journal of the American Medical Association.

2. By printing and distributing over forty thousand copies of said plan, accompanied by the necessary explanations, and blank pledges asking the return of the latter to the president of the board.

3. By ascertaining, as reliably as possible, the cost of publishing the journal on the plan agreed to do.

4. By assembling at the proper time and in open meeting, carefully canvassing the results, and arriving unanimously at the conclusion that the publication of the proposed journal on the general plan already stated could be undertaken, not only without serious danger of producing any financial embarrassment, but, on the contrary, with a fair prospect of greatly adding to the prosperity of the association by retaining in active connection with it all who may be added from year to year, and by keeping alive a very much more active and beneficial intercourse with the profession at large; and

5. By a cordial agreement upon the general plan of business management, the most favorable place for publishing, and upon the chief editor, to take charge of the work, provided the association should accept the recommendations and order it to proceed.

The expenses incurred by the board were \$709.

In conclusion, the following resolutions are submitted for your consideration and action thereon:

Resolved, That the Report of the Board of Trustees just read be accepted, and the recommendations contained therein concerning the publication of a weekly periodical, to be called

the 'Journal of the American Medical Association,' be and the same are hereby adopted.

"*Resolved*, That the Board of Trustees are hereby instructed to proceed with the publication of the 'Journal of the American Medical Association' at as early a day as is practicable, to take the place of the annual volume of 'Transactions,' and that the duties formerly devolved upon the standing Committee on Publication be transferred to the Board of Trustees, and that the secretary of the association, during or immediately after each annual session, be required to transfer to the editor of the Journal the record of proceedings, and all addresses, with reports of committees and officers, papers and contributions that may be referred for publication, either in general sessions or in any of the sections.

"*Resolved*, That the treasurer of the association be and is hereby directed to make such arrangements with the Board of Trustees in regard to the collection of subscriptions and the disbursement of moneys as may be necessary for facilitating the business of publishing a weekly medical journal. But all orders on the treasury for disbursements of money in any way connected with the publication must be indorsed by the president of the Board of Trustees."

Dr. WILLIAM BRODIE, of Michigan, moved the adoption of the resolutions.

Dr. W. C. WILE, of Connecticut, in view of the importance of the subject, moved as an amendment that the secretary be instructed to have the report printed, and that its discussion be postponed until to-morrow morning at ten o'clock. The amendment was lost. The resolutions were then adopted.

Dr. L. S. McMURTRY, secretary of the Board of Trustees, announced that the board had unanimously selected Dr. N. S. Davis as editor in chief of the journal. Dr. Davis expressed his thanks for the honor, and promised to use his best efforts for the success of the journal. He tendered his resignation as a member of the Board of Trustees.

Dr. A. B. PALMER, of Michigan, expressed his pleasure with the report, and spoke briefly in praise of Dr. Davis. Dr. Davis announced that he had engaged Dr. William Lee, of Washington, to take charge of the department of medicine in the journal, and that other assistants would be secured as soon as possible.

Dr. J. SOLIS COHEN, of Pennsylvania, moved that the Board of Trustees for the publication of the transactions of the American Medical Association be instructed, in addition to the journal, to print annually a thin octavo volume containing the minutes of the association. The motion was seconded by Dr. Quinby of New Jersey. Drs. Hibbard, of Indiana, and Byrd, of Illinois, hoped it would not prevail. Dr. Richardson moved to refer the question to the Board of Trustees. Carried.

On motion of Dr. Bush, of Delaware, a vote of thanks was tendered to Dr. Davis for the faithful discharge of his duties.

THE NEW BOARD OF TRUSTEES.—Dr. Davis having made a formal acceptance of the editorship of the journal, and resigned his position as a member of the board, there remained four vacancies in the board. Upon motion of Dr. Richardson, of Louisiana, the chair was authorized to appoint a nominating committee to fill said vacancies. The chair appointed as such committee Drs. Richardson, of Louisiana; Brodie, of Michigan; Hibbard, of Indiana; Baldwin, of Alabama; and Scott, of Ohio.

The committee reported the names of Drs. G. O. Hooker, of Arkansas; Alonzo Garcelon, of Maine; L. S. McMurtry, of Kentucky (re-elected); and Dr. J. H. Hollister, of Illinois, to fill Dr. Davis's place.

THE ROCKY MOUNTAIN MEDICAL ASSOCIATION.—The secretary announced that this association would meet at the Weddell House in the evening. He stated that the association consisted of a party of physicians who, some eleven years ago, accompanied by

their wives and sweethearts, crossed the mountains to attend the meetings of the American Medical Association at San Francisco.

THE ADDRESS IN MEDICINE.—Dr. J. H. HOLLISTER, chairman of the Section in Practical Medicine, was then introduced, and read an address on the Development of Medical Science since the last meeting. He said: "Men have been compelled to grapple with some of the most intricate and difficult problems that can challenge investigation. In studying those higher relations which lie in part beyond the limits of finite conception, reason may properly defer to faith, and, seeking the guiding hand of revelation, walk with a wisdom other than its own. But in medicine it is not so. Forces, mental and material, and interchangeable, manifest themselves in ways so manifold, and with so many essential facts undiscovered, that reason is compelled to thread her way with steps slow and uncertain, sometimes in truth, oftentimes in error, ever painfully conscious of her weakness, and of the mysteries that confront her on every side.

"Thus only may we account for the seemingly meager fruitage which represents for more than two thousand years the labors of some of the ablest minds the world has ever seen."

He further said that the essential causes of disease had in the main been so obscure, and their expressions so varied and complex, that the best of men had been compelled to conclusions largely inferential, and medicine had ever been the fruitful field, in the absence of positive knowledge, for exuberant development. Speculations had been piled mountain high by one generation of workers, to disappear before another as chaff. But, despite the winnowings, there still remained some golden grains of truth, and the treasure-house had been slowly but surely enriched by the garnering of ages.

He then went on to show some few things that had been done by the present army of brilliant workers. He spoke of the value of the microscope in determining the truth of the germ theory of disease. It opened up new fields every day. He gave the limit of measurement now attained as the $\frac{1}{100,000}$ part of an inch, arguing that it was idle to speculate as to when or where the limits of human vision would finally fall. In microscopy, two subjects more than any other command attention at this time. The first one was the composition of the blood; the second, the agency of microzymes in the production of diseases. He mentioned the difficulty of deciding which possessed the most vitality—the bacteria or the blood corpuscles—and the danger in pursuing the germicidal treatment—of killing the subject while the bacteria remained unharmed, like the surgeon who saved the tumor but killed the man.

He recommended that in the course of time a national board of medical examiners be appointed, who alone should grant permission to practice medicine, suggesting that this would stop the yearly grist of the diploma mills. He said he was happy to announce that a law had just come into force in Italy which prohibited the sale of patent medicines unless their precise composition was stated. This statement was received with loud applause. The speaker also recommended the establishment of a medical bureau.

THE ADDRESS IN OBSTETRICS.—Dr. J. K. BARTLETT, of Wisconsin, chairman of the Section in Obstetrics, was unable to present his address personally, on account of throat difficulty, and asked that Dr. Nicholas Senn be allowed to read it. The address recounted the many advances made in obstetrical operations. As a process of destroying the fetus, it mentioned the occasional use of electricity in cases of extra-uterine pregnancy—an anomaly which could only result in the death of the mother unless an operation was performed. He also related cases where blood, milk, and saline solutions had been transfused for post-partum hemorrhage. He deprecated the frequent use of the forceps, and said that he had arrived at the conclu-

sion that its use had been of far more injury than benefit. He also described a number of mechanical contrivances for aiding childbirth. He then alluded to the use of ergot in labor, suggesting some reasons for the wide difference in opinion which existed with regard to its employment in obstetrics.

Dr. Bartlett's address was received with considerable applause, and was referred to the Committee on Publication.

THE REPORT ON NECROLOGY.—Dr. TONE, of Washington, chairman of the Committee on Necrology, handed in a report of the names of members of the association who had died within the past year, and, on his motion, the report was ordered published.

The meeting then adjourned till Thursday, at 9.30 A. M.

Thursday—Third Day.

The Rev. N. S. RULISON, of St. Paul's Church, read a passage from the Scriptures, and offered a prayer.

DELEGATES TO THE BRITISH MEDICAL ASSOCIATION.—The secretary announced that the president had appointed certain gentlemen as delegates to the British Medical Association and other scientific bodies in Europe, and requested those who were to go abroad to come to him and get their appointments.

AN AMENDMENT TO THE BY-LAWS.—Dr. KELLER, of Arkansas, called up an amendment to the by-laws offered by him last year, giving power to the association, through the Committee on Nominations, to fix the time and place of meetings, and moved its adoption. The motion was seconded and the amendment was adopted.

LAWS CONCERNING THE SALE OF POISONS.—Dr. D. H. BACHELOR, of Rhode Island, offered the following:

Whereas, In the opinion of this association the laws of almost every State are too lax in regard to the sale of toxic agents, by which suicidal deaths are made easy; therefore,

Resolved and voted, That there be appointed by the president one or more persons or members from each of the States, who shall be members of this association, to confer with the Legislature of each of the States, by petition or otherwise, for the enactment of more stringent laws in relation to the sale of all toxic agents.

Dr. Bachelor, in support of his resolution, said that scarcely a day passed that some one did not end his days by taking poison, and called earnestly upon the meeting to exert its influence to secure the passage of laws restraining and limiting the sale of poisonous drugs. The resolution was unanimously adopted.

A TRIBUTE TO THE LATE DR. FARR.—The following resolution was offered by Dr. FOSTER PRATT, of Michigan: *Resolved*, That the labors of Dr. William Farr, of England (recently deceased), in the organization, classification, and compilation of vital statistics—labors begun in 1828, and afterward perseveringly, wisely, and ably continued by him for nearly half a century—are recognized by the medical profession of the United States as an enduring monument to his ability and learning as a physician; as the real initiation and foundation of our own sanitary work; and as a perpetual blessing to present to future generations of our universal humanity, entitling his name and fame to stand with that of the great men whose genius and labors have resulted in beneficial revolutions of the medical, surgical, and sanitary thought and activities of the civilized world.

Dr. Pratt stated that the foregoing resolution was passed by the section in state medicine, and referred to the association, with the request that it be adopted. On motion of Dr. Pratt, the resolution was read was adopted.

TRAINING SCHOOLS FOR NURSES.—Dr. S. D. GROSS, of Pennsylvania, offered the following preamble and resolution:

Whereas, Good nursing is of paramount importance to the

comfort of the sick and to the restoration of their health; and

Whereas, The subject is one which strongly addresses itself to the common sense and kindly sympathy of every intelligent member of society. Therefore be it

Resolved, That this association, fully recognizing the importance of the subject, respectfully recommend the establishment at every county town in our States and Territories of schools or societies for the efficient training of nurses, male and female, by lectures and practical instruction to be given by competent medical men, members, if possible, of county societies, either gratuitously or at such reasonable rates as shall not bar the poor from availing themselves of their benefit.

In support of the resolution, Dr. Gross said: In all our larger cities there are training schools, but in the rural districts of our country no such institutions are to be found. Associations for carrying out this plan can be easily organized in every county by the county societies. Two or three members could be intrusted with this duty, and in this way, in the rural districts, we could have in a comparatively short time excellent nurses.

The resolution was adopted.

A PROPOSED SECTION IN PSYCHOLOGICAL MEDICINE.—Dr. WALTER HAY, of Illinois, offered a resolution providing for the formation of a special section in psychological medicine. Laid over under the rules for one year.

REPORT OF THE COMMITTEE ON METEOROLOGY.—Dr. N. S. DAVIS, of Illinois, next presented the report of the Standing Committee on Atmospheric or Meteorological Conditions and their relations to prevalence of acute diseases. Dr. Davis said that the committee began its work on the 1st of January, 1882, to secure the results of three parallel series of coincident observations in twelve different localities. One series consisted of the observations and records made at the signal-service stations in the twelve localities named: Boston, New York, Philadelphia, Baltimore, Newport, New Orleans, Cincinnati, Chicago, St. Paul, Pittsburg, Denver, San Francisco, and Lansing, full abstracts having been furnished to the chairman under the order of the head of the Signal-Service Bureau. Another series consisted of a daily record of the ozone or active oxidizing agents in the atmosphere in the same localities, made by scientific men, whose names were given in the report of last year. In most of the places this series of observation was continued through the year of 1882. The results were tabulated by Professor Long, and formed a part of this report. To this series was also added in Chicago a daily record of the organic or albuminoid matters in the atmosphere, this being the first record of reliable determinations of the quantity of organic matter in the atmosphere made daily in this or any other country during the year.

The third series of observations consisted in ascertaining and recording the date of commencement of all acute diseases, in order to determine their real causes, by physicians in active practice in the same localities where the other series of observations were in progress.

The facts, as observed, collated, and recorded, were considered very important. Reference was here made to Professor Long's report, in which a description was given of the method of making these observations. Following Professor Long's report, Dr. Davis presented a statement of the expenses incurred by the committee, and ended by asking, on behalf of the committee, that the association adopt various propositions: First, that the committee be authorized to furnish their report for publication as a part of the Transactions of the association; and to continue the investigation now in progress, with the privilege of drawing on the treasure for so much of the unexpended balance of former appropriations as might be necessary

for the coming year. Second, That the thanks of the association be tendered to the Superintendent of the Signal-Service Bureau, General Hazen, for the generous aid rendered in furnishing the committee with full abstracts of meteorological records made at the several places selected, and also that a continuation of the same favor be requested during such time as the committee might desire.

Dr. DIDAMA's resolution of Tuesday, for the making of reports of the meteorological condition of the various health resorts of the country, was taken from the table, and, on motion, referred, together with the resolutions contained in Dr. Davis's report, to the Committee on Atmospheric Conditions. By request of Dr. Davis, Dr. Didama was made a member of the committee.

THE LATE DR. HUBBARD.—Dr. REED, of Iowa, offered a resolution extending the sympathy of the association to the wife and family of Dr. J. C. Hubbard, of Ashtabula, Ohio, who died while in attendance upon the meeting. It was adopted.

DELEGATES TO FOREIGN ASSOCIATIONS.—The secretary read a list of delegates appointed by the president to represent the association at meetings of foreign associations, as follows: G. J. Engelmann, of Missouri; W. M. Finley, of Pennsylvania; Walter L. Zeigler, of Pennsylvania; M. H. Alter, of Pennsylvania; R. B. Cole, of California; J. H. Warren, of Massachusetts; C. H. Von Klein, of Ohio; W. M. Lawler, of California; Henry A. Martin, of Massachusetts; J. C. Hutchison, of New York; A. M. Hawes, of Michigan; Edward Borck, of Missouri; T. F. Prewitt, of Missouri; E. T. Allen, of Pennsylvania; H. McCall, of Michigan; J. N. Quinby, of New Jersey; S. C. Gordon, of Maine.

A PROPOSITION TO REVISE THE CODE OF ETHICS.—Dr. POLAK, of St. Louis, at the request of the St. Louis Medical Society, offered the following:

A code of ethics is considered essential for such an organization as the American Medical Association, and is equal in importance to the written law of a community. Associations and communities can only be ruled by laws which are made for themselves and by themselves. But the best laws became oppressive and inoperative when the conditions changed which called for their enactment.

A revision and change of such laws becomes then imperative, as is so frequently instanced by the changes of the Constitution of the United States, and of that of every State in the Union. Municipal and corporation charters are changed by the will of the government, which delegate that power to their representatives.

The code of ethics has an existence coeval with the organization of the American Medical Association. It was absolutely necessary then, and it can not be entirely dispensed with now. But in thirty-four years this country has presented so many phases in its development and progress that new laws are being constantly enacted, and old laws are repealed or modified to suit the requirements of the time.

The code has accomplished all it was designed it should, but at present many of its features are obsolete, and not adapted to our wants. The necessity of an early revision is very apparent, is loudly called for in all parts of our land, and can not be repressed much longer. The American Medical Association alone has the right and the power to order a revision; all other medical organizations in affiliation with it can only respectfully ask for it. The time has come when the loud and very soon universal call should be heeded. The excitement and the evil consequences of a schism can be easily averted now, and harmony and fraternal feeling may once more be restored among the members of the medical profession. Therefore

Resolved, First, That the American Medical Association be

respectfully requested to appoint a committee of one member from each State for the purpose of taking into consideration the propriety and advisability of a revision of the code of ethics, and to report thereon at the meeting of 1884.

Second, That the committee be authorized to prepare a code of ethics which in their view will meet the wishes of the profession, and submit the same to the meeting of 1884.

This was tabled under the rule for one year.

THE SELECTION OF PAPERS TO BE READ.—Dr. WILLIAM BROMIE, of Michigan, offered the following resolution:

Resolved, That all papers to be read before the different sections shall, before their reading, have the approval of the chairmen of the same.

Dr. KELLER moved that the resolution be laid on the table. Carried.

A MEMBER BY INVITATION.—Dr. N. S. DAVIS, of Illinois, moved that Dr. M. L. Nardyz, representing several foreign associations, be elected a member of this association by invitation. Carried.

THE ADDRESS IN SURGERY.—Dr. W. F. PECK, of Iowa, chairman of the section on surgery and anatomy, delivered an address, of which the following is a synopsis:

Mr. President and Gentlemen of the Association: In performing the duties of chairman of the surgical section, it is not deemed practicable to compass all that the organic law of the association may contemplate. For in reporting upon the progress made in surgical science it is recognized that many theories are at present announced as facts which, when experience and demonstration shall have thoroughly tested them, may be eliminated, perhaps to reappear when the cycle of professional experience again completes its revolution.

The greatest progress has been made in operative surgery, although other departments have been constantly endeavoring to add new light to the already extensive accumulations. Since Cohnheim gave to the profession, in a complete and formulated manner, the character and importance of the colorless corpuscle in pathological changes, strenuous efforts have been put forth by Pasteur, Koch, and others to unfold the importance of the bacterial germs which, according to demonstrations by Oliver and others, have a normal existence in the blood, the lymph, and the tissues of the body. The surgeon is much interested in these investigations, because of the important statements made by eminent teachers concerning the origin and nature of some forms of articular disease, also the peculiar degeneration which takes place in bone and glandular structures. The interest does not stop with these tissues, for underneath it all the germ theory, which is thought by many excellent men to deal with the greatest of all causes for engendering infectious inflammations, pyæmia, septicæmia, abscess, gangrene, etc., receives a support which, if sustained, will tend to give new and more efficient reasons for the use of antisepticism in practice. It can not be admitted that practical surgery has thus far been directly benefited by Koch's views.

The condition of the problem of the management of wounds and other pathological processes by means of the so-called antiseptic methods suggests a move in the direction of greater confidence in the details of operative procedure, and scrupulous attention to extreme cleanliness in the minutæ of practice. Within the year the antiseptic methods of wound manipulation have been regarded as embracing the spray, the fixed and intimate relations of fresh surfaces, rest, pure-air surroundings, and, when practicable, drainage. While it is admitted that most of the leading surgeons of England are thoroughly wedded to the antiseptic treatment of wounds, there are to be found not a few excellent teachers who reverently believe that nature, under wise assistance from the surgeon, will do more to save life

and limb than the surgeon can do who depends upon strict antisepticism.

It is apparent that the "lost art of bloodletting" in the treatment of inflammation is being reclaimed, and that its induction into a legitimate position among other remedies of conceded value is fast taking place.

Among the many new and important instruments which have been presented may be mentioned the universal or compound racket joint, offered by Dr. Stillman, which can be adjusted at pleasure and permit universal motion.

Perhaps one of the most important steps that have been taken is the utilization of the electric light as a means of diagnosis, and as an aid in performing operations in cavities and places where natural light can be used only with uncertain effect.

Dr. Peck here gave details of many interesting cases illustrative of progress in abdominal surgery, among them one published by Léon Le Fort, of France, who, in June, 1882, was called to see a man, eighteen years of age, seized on the evening of May 25th with severe pain in the abdomen, becoming more like colic about midnight, for which Dr. Tachard gave laudanum and belladonna, and used hot poultices, some relief being received. Next day the pain increased, with special sensitiveness of the abdomen and some tympanites. Castor-oil was given, but was immediately vomited. No evacuation of the bowels could be produced, but vomiting and retching became incessant. There was a small left inguinal hernia, which played, however, no part in the case. Three years before there had been peritoneal inflammation. On June 1st, decided typhoid symptoms appearing, an incision about fifteen centimetres in length was made from just above the pubes to near the umbilicus. The intestines rolled out, and were carefully examined, coil by coil, and returned. Upon meeting with slight resistance when making traction upon a portion of the ileum, the hand was passed along the bowel to the right iliac region, where a constricting ring or band of fibrous tissue was found, which was thick, formed of organized adhesions, and encircling the small intestines for a distance of five centimetres from the cæcum. The width of the band was five millimetres. The constriction was divided by means of scissors, and the intestines were liberated. There were some evidences of congestion, but there was no decided inflammation. The life of the tissues not having been compromised, the parts were thoroughly cleansed and returned, and seven deep silver-wire sutures were passed through the deep tissues and fastened on the opposite sides to bougies. Superficial sutures were employed to retain the surface edges in coaptation. On the night of June 1st there was a spontaneous evacuation of the bowels. On the seventh day the patient subjected the abdomen to undue exertion, when the superficial sutures gave way. They were replaced, and thereafter uninterrupted recovery followed. On July 1st he was well. The general management of the operation was not antiseptic. The man's health seven months after the operation was much better than before, and there was no longer any hernia.

Dr. Peck described, also, a new operation performed by Professor Pietro Loretta, of Bologna, for stenosis of the pylorus. He continued: At present, attention is being particularly called to the kidneys in relation to operative surgery, and doubtless there is ample room for a profitable interchange of opinions and experience. To what extent defective organic action, associated with anæsthesia, is due to the insufficient vitality of the blood, careful future observation only can determine. It is not enough to say that, in any given case, death occurred as a result of fibrin collected on and around one or more of the heart valves. There must be a further cause which influences the dyscrasial condition of the blood.

Dr. David Newman, of Glasgow, has performed the operation of nephrorrhaphy, being the first operation of the kind done in Great Britain, upon a woman for floating kidney. The renal capsule was stitched to the margins of the incision, and deep button-sutures were passed through the kidney substance, thus fixing the organ in its natural position. The patient recovered.

Important additions have been made to our surgical literature, in monographs and revised editions of leading text-books, and in America the profession may be congratulated upon the appearance of two important volumes—one the new volume of the "Medical and Surgical History of the War of the Rebellion"; the other a part of a "Treatise on Human Anatomy," by Dr. Harrison Allen, of Philadelphia.

A rare and most substantial advance is being made in surgery in connection with railway corporations, which will result in the accumulation of a vast amount of statistical information of great service in neural pathology. The surgical bureaus of these corporations will, by their collected experience and tabulations, be qualified to furnish much valuable information to both judicial and popular tribunals. Then justice to pathology and rewards to individuals will receive fairer and more honorable administration.

Dr. Peck's paper was listened to with marked attention by the meeting, and, at the conclusion of its reading, it was referred to the Committee on Publication.

THE ADDRESS IN STATE MEDICINE. The address by the chairman of the section on state medicine, Dr. FOSTER PRATT, of Michigan, was very interesting, but, owing to lack of space, we can give but a meager report of it. He said:

Mr. President and Members of the Association: Your by-laws require from the chairman of each section a paper on the "advances and discoveries" of the past year in the branches of science included in his section. The somewhat undefined boundaries of the section of state medicine and the purely practical nature of that part of its scientific domain which is defined make the task of the chairman not a little embarrassing.

The speaker here made brief reference to the various topics assigned to his section, stating that psychology, insanity, medical jurisprudence, and medical expert evidence had each received during the year the attention to which they were severally entitled, adding that there had been no noteworthy advance in any of them, and asking the question, which was suggested by recent pathological inquiries, What, if anything, may be done by systematic effort to prevent insanity? He further stated that expert medical testimony occupied an uncomfortable and undignified relation to American law and practice, for which at present there did not seem to be any hope of relief, and suggested that, when our law of trials permitted courts to determine who were experts, and call them to testify for science, relieving them from the appearance of testifying for one side or the other, their evidence would command, more thoroughly than now, the respect and confidence of courts, juries, the parties, and the people. He proposed to apply some other term to his section than state medicine, as the present term required elaborate explanation, adding that, perhaps, by calling it the section of public health, its nature would be more clearly defined; but names, titles, and designations, whether fortunate or unfortunate, had not prevented, and would not prevent, the progress of this latest manifestation of medical philanthropy.

This section of state medicine was established in 1873, since which time a great amount of systematic sanitary work had been accomplished with State aid. Sanitary organizations had been formed and developed, as well as State and local boards of health, which had been educated in some degree for their special work, and to-day intelligent and scientific attention was

paid, as never before, to the hygienic construction of houses, shops, and public buildings. It was easy to see that the people were emancipating themselves from the thralldom that had held them paralyzed and helpless in the presence of epidemics and fatal scourges. They were beginning to learn that the seeds of many diseases and their propagation and diffusion were governed by laws, and that by observing the sanitary laws they might in a measure escape fatal results. They were beginning to understand that the curse did not come causeless—that physical laws might be ignorantly broken without moral guilt, though not without punishment. Prior to 1873 but two States in the Union had established State boards of health—Massachusetts and California. Since that time twenty-five other States had inscribed "Sanitary Reform" on their banners, which practically proclaimed that the safety of the people was the supreme law—that public health was public wealth—that to promote the health of the people was the first duty of statesmen. Not many years would pass before every State in the Union would be engaged in organized effort to battle with the unnecessary ills and evils that tortured humanity and enfeebled the State. Facts had demonstrated that small-pox could be prevented. Small-pox in the popular mind stood at the head of dangerous and dreaded diseases by reason of its communicability and loathsomeness. It also stood, thanks to Jenner's grand discovery, at the head of preventable diseases.

The speaker here referred in glowing terms to the late Dr. William Farr, the great vital statistician of England, who died some weeks ago. Even our best men, he continued, were liable to be thrust aside as visionary theorists, or perhaps as "salary grabbers," in the words of the congressional debates; but our Davy Crocketts in effect said to us: "Be sure you are right, then go ahead." But we must win the legislators to our side that were not now with us in justifying the organization of State boards of health.

The first successful movement made in Massachusetts and in the United States in the direction of State sanitation was instigated by a lady. Women had a great stake in this sanitary movement. The cynical and incredulous would ask, perhaps, "How many lives per annum do you save?" To this, as yet, we could only answer, "We do not know. Our own statistics have not been carried far enough." But this we did know, that, whereas, by Dr. Farr's tables, the average duration of human life in England thirty years ago was for males 39 $\frac{1}{10}$ years; it was now, after only seven years of organized sanitary work, 41 $\frac{1}{10}$ years—an addition of full two years to the duration of male life in all England. The effect on the average of female life was still more striking, adding nearly three years and a half—all these results after only a few years of work. Who here could doubt that the result in England would be essentially duplicated in America? Our public health work was yet in its infancy, and much remained to be done. He would here call attention to the remarkable unanimity with which State medical societies, State boards of health, the American Public Health Association, this American Medical Association, and the medical profession generally had expressed their approval of the organization and the action of the National Board of Health. The only valid objection ever urged to its formation, or rather its possible action, was that based on constitutional questions. On this question the people would soon decide in whose hands they prefer to intrust their health and lives and commercial interests, but it was gratifying to know that medical sentiment was nearly unanimous for a national board.

The speaker referred to the recent discoveries of the tubercle bacillus and to the evidence produced, that it was the specific germ by which tubercular phthisis was produced and might be transmitted, and, in closing, said we seemed, indeed, to be on

the eve of great discoveries in etiology and pathology, which without doubt must greatly increase our practical knowledge and improve our treatment of many important maladies. As medical practitioners, if we could not individually help to hasten the anticipated result, we could help to swell the multitude who were anxiously waiting for it. But as medical legal sanitarians, impatiently waiting for newly and firmly established truth, on which to build improved hygienic and sanitary methods, we, metaphorically, held our breath.

During the reading of this paper the speaker was frequently interrupted with applause.

REPORT OF THE TREASURER.—The treasurer, Dr. RICHARD J. DUNGLISON, of Pennsylvania, submitted his report, showing a balance on hand of \$903.93. The report was accepted.

REPORT OF THE LIBRARIAN.—The librarian, Dr. C. H. A. KLEINSCHMIDT, of the District of Columbia, then reported that the whole number of volumes and pamphlets in the library of the association was 5,713, and recommended that home and foreign exchanges be requested to contribute their publications; and, further, that a hundred dollars be placed at his disposal for the purpose of replacing the binding of books. This report was also accepted.

REPORT OF THE COMMITTEE ON NOMINATIONS.—The Committee on Nominations then reported, with the following results: President, Austin Flint, Sr., of New York. This was received with deafening applause. Vice-Presidents, R. A. Kinloch, of South Carolina; T. B. Lester, of Missouri; A. L. Gihon, of the navy; S. C. Gordon, of Maine; Treasurer, R. J. Dunglison, of Pennsylvania; Librarian, C. H. A. Kleinschmidt, of the District of Columbia. The place of meeting for 1884, Washington, on the first Tuesday of May. Chairman of the Committee of Arrangements, A. Y. P. Garnett, of Washington; Assistant Secretary, D. W. Prentiss, of the same city. Judicial Council, F. D. Cunningham, of Virginia; H. O. Marcy, of Massachusetts; W. O. Baldwin, of Alabama; J. S. Billings, of the army; Freeman W. Miller, of the Marine-Hospital Service; Eugene Grisom, of North Carolina; R. N. Todd, of Indiana; to fill vacancy in Judicial Council for class of 1884, E. W. Clark, of Iowa. The names of the chairman and secretaries of the various sections were then read as follows: Practice of Medicine—Chairman, J. V. Shoemaker, of Pennsylvania; Secretary, W. C. Wile, of Connecticut. Obstetrics and Diseases of Women—Chairman, T. A. Reamy, of Ohio; Secretary, J. T. Jelks, of Arkansas. Surgery and Anatomy—Chairman, C. D. Parkes, of Illinois; Secretary, H. O. Walker, of Michigan. Ophthalmology, Otology, and Laryngology—Chairman, J. J. Chisolm, of Maryland; Secretary Thompson, of Indiana. Diseases of Children—Chairman, William Lee, of Maryland; Secretary, W. R. Tipton, of New Mexico. Dental and Oral Surgery—Chairman, T. W. Brophy, of Illinois; Secretary, John S. Marshall, of Illinois. State Medicine—Chairman, D. J. Roberts, of Tennessee; Secretary, Franzoni, of the District of Columbia. The Committee on State Medicine consists of one member from each State of the Union, as follows: Alabama, Jerome Cochran; Arkansas, J. J. McAlmont; California, W. F. McDermott; Colorado, Charles Dennison; Connecticut, C. W. Chamberlain; Dakota Territory, J. B. Van Nelsor; Georgia, J. P. Logan; Illinois, O. C. De Wolf; Indiana, George Sutton; Iowa, W. S. Robertson; Kansas, D. W. Stormont; Kentucky, J. P. Thompson; Louisiana, S. C. Chailé; Maine, S. H. Weeks; Maryland, John Morris; Massachusetts, H. I. Bowditch; Michigan, F. K. Owen; Minnesota, C. N. Hewitt; New Mexico, M. M. Milligan; District of Columbia, S. Townsend; Delaware, L. P. Bush; Oregon, H. Carpenter; Mississippi, H. H. Gault; Missouri, Lester Hall; Nebraska, L. B. Larsh; New York, E. M. Moore; New Jersey, Ezra M. Hunt; North Carolina, James McKee; Ohio, T. L. Neal; Penn-

sylvania, R. J. Darglison; Rhode Island, C. H. Fisher; Tennessee, C. C. Fire; Texas, Thomas C. Wooten; Vermont, S. W. Thayer; Virginia, J. L. Cabell; West Virginia, Moffit; Wisconsin, J. T. Reeve; the Army, J. R. Smith; the Navy, J. M. Brown; the Marine-Hospital Service, P. H. Bailhache; South Carolina, Manning Simmons.

A COMMUNICATION FROM THE PRESIDENT-ELECT.—Dr. DIMA MA, of New York, a member of the Nominating Committee, read the following letter from the president-elect:

"Circumstances render it necessary for me to return early to-day to New York. Will you kindly express to our brethren, the members of the American Medical Association, with my sincere thanks, an assurance that I thoroughly appreciate the great honor which has been conferred upon me.

"I accept the honor, feeling assured that I may confidently expect co-operation and indulgence in my efforts to fulfill the duties which it involves.

"Yours, very truly,

"AUSTIN FLINT."

The secretary read a letter from Dr. A. L. Gihon, of the navy, which stated that he was a firm believer in the code of ethics in all its parts.

President Atlee here tendered his thanks to the ladies for the beautiful basket of flowers sent him.

Friday—Fourth Day.

The Rev. CHARLES TERRY COLLINS opened the session with a prayer.

PROPOSED AMENDMENTS TO THE CONSTITUTION.—An amendment to the constitution, submitted last year by Dr. N. S. Smith, of Dakota Territory, was taken up and acted upon as follows:

"To provide for the admission to membership of two delegates from the Medical Bureau of the United States Indian service, to be nominated by the surgeon-in-chief of that bureau and approved by the Secretary of the Interior." This amendment was tabled.

The amendment offered by Dr. J. M. Toner, of the District of Columbia, in relation to the office of permanent secretary being abolished, and hereafter annually nominating a secretary to serve without compensation, was withdrawn by that gentleman.

The amendment offered by Dr. J. H. Sears, of Arkansas, that the chairman and secretary of each section may add any number of earnest workers to their section, in addition to those named by the Nominating Committee, and that the librarian be made a permanent officer, was tabled.

The amendment offered by Dr. J. W. Smith, of Iowa, to the by laws, Article II, section 8, to strike out the words "but without the right of voting," was then taken up. After some discussion, action on the amendment was indefinitely postponed.

ADDRESSES DISPENSED WITH.—The address by the chairman of the section in Diseases of Children, Dr. R. F. BLOUNT, of Indiana, and that of the chairman of the section in Dental and Oral Surgery, Dr. D. H. GOODWILLIE, of New York, were not read, but referred to the Committee on Publication. On motion, the reports of secretaries of sections were referred to the Board of Trustees.

The PRESIDENT announced the appointment of Dr. William Brodie and Dr. H. L. Walker as delegates to attend the meeting of the Canadian Medical Association.

REPORT OF THE JUDICIAL COUNCIL.—Dr. N. S. DAVIS made the following report on behalf of the Judicial Council:

In regard to the petition of Dr. D. W. Day, asking for a rehearing of his case, which was adjudicated last year, the council had ordered the return of the petition of Dr. Day, with leave granted to supplement said paper by a written statement of

the character of the new evidence which he proposes to introduce, and the council had declined to act upon the case until the opening of the session next year, from the impossibility of notifying all the parties concerned.

In the case of Dr. D. H. Goodwillie, the council had decided that the registration of Dr. Goodwillie should be canceled, and the annual dues be returned to him.

THE MERCANTILE MARINE MEDICAL SERVICE.—Dr. A. N. BELL, of New York, offered the following resolution, passed in the session of the section in state medicine, and referred to the association:

Being impressed with the truthfulness and importance of the Memorial of the Parliamentary Bills Committee of the British Medical Association, under date of March 17, 1883, the American Medical Association urge upon the Congress of the United States the subject of competent medical and sanitary service, and proper provision for its maintenance, on board all transoceanic passenger vessels, and that a committee of five be appointed to promote this object, and to report upon the condition of the subject at the next session.

PAPERS READ BEFORE THE SECTIONS.—Dr. BELL also offered the following preamble and resolution:

Whereas, The practice prevails of reading papers before the several sections at the option of their authors, without sufficient regard to the special objects for which the sections were created, therefore,

Resolved, That all papers hereafter offered or intended to be read before the association or any of its sections, except the address of the president and the chairman of the sections, shall be first referred to the trustees of the journal for classification and appropriate reference. Tabled.

The PRESIDENT announced the following Committee on Surgical Service aboard steam and other ocean vessels: A. N. Bell, of New York; A. L. Gihon, of the navy; J. N. Quinby, of New Jersey; H. O. Marcy, of Massachusetts; Henry H. Smith, of Pennsylvania.

THE LATE SURGEON-GENERAL BARNES.—Dr. WILLIAM BRODIE, of Michigan, offered the following resolution:

Whereas, This association takes a deep interest in the efficiency of the Medical Department of the United States Army; and

Whereas, The late chief of this department, Surgeon-General Joseph K. Barnes, contributed largely to the efficiency of this department in the work which it has been and is doing for medical science and education, therefore,

Resolved, That this association receives with profound regret information of the death of General Barnes, and desires to record its appreciation of the great value and importance of the work which he has done, and enabled others to do, for the advancement of medical science.

Resolved, That this association recognizes the energy and ability which characterized the administration of General Barnes, and his services in connection with the Army Medical Museum and Library, and the publication of the "Medical and Surgical History of the War," and other works of great value to the profession.

Resolved, That a copy of these resolutions be sent to the Surgeon General of the army. Adopted.

CREMATION.—Dr. J. M. KELLER offered the following resolution: That in the very near future, if not now, cremation will be done as a sanitary necessity in the large cities and popular districts of the country. Referred to the section in hygiene.

A vote of thanks was tendered to the secretary and treasurer for their efforts and the satisfactory manner in which they have severally discharged their duties.

THE EXAMINATION OF RAILROAD EMPLOYÉS.—Dr. TURN-

BULL, of Pennsylvania, offered the following: *Resolved*, That the Legislature of each State be petitioned at its annual session to pass a law requiring all railroad employes to be examined with reference to acuteness of hearing before taking charge of any railroad trains or tracks. Laid over for a year under the rule.

CLOSING REMARKS BY THE PRESIDENT.—The PRESIDENT said: Gentlemen: I am about to vacate the chair with which you have honored me, and in doing so I do it with the greatest possible satisfaction. I expected to have the honor of inducting into the chair a gentleman who certainly is in every respect most worthy of it [applause]—a gentleman who has done as much for the medical literature of the country as almost any other, and one whom I characterized a few days ago, in a very different place, the Laennec of America. I most heartily thank you for the support you have given me, and I can only say that I hope you will forgive my shortcomings. I bid you an affectionate farewell. [Prolonged applause.] Just before we adjourn, gentlemen, I will introduce to you the Second Vice President, Dr. Lester, in the absence of the President and First Vice-President.

Dr. GARCELON, of Maine, offered the following resolution:

Resolved, That the thanks of this association be extended to Dr. J. L. Atlee, the retiring President, for the able, dignified, and satisfactory manner in which he has presided over the deliberations of the association, and that he retires with the best wishes of every member of this association for the long continuance of a life so highly useful not only to the present, but to all future generations. Adopted unanimously.

Dr. Lester then declared the association adjourned, to meet in Washington the first Tuesday in May, 1884.

MASSACHUSETTS MEDICAL SOCIETY.

THE one hundred and second annual meeting was held in Boston on Tuesday and Wednesday, June 12 and 13, 1883.

Tuesday—First Day.

The morning having been spent in inspecting exhibits of sanitary appliances and in visiting the various hospitals, the meeting was called to order at twelve o'clock by the Vice-President, JOHN H. MAOKIE, M. D., of New Bedford.

A CONTRIBUTION TO THE STUDY OF THE TUBERCLE BACILLUS.—Dr. H. C. ERNST, of Jamaica Plain, read an interesting paper with this title. He gave a *résumé* of the work done by various foreign experimenters, described the bacillus, and gave the process of its preparation for examination. He then reported a series of twenty-five observations made by himself, and stated as a result that the tubercle bacillus was always present in tuberculosis, but that it was not present in caseous phthisis; that the bacteria were present in tubercular disease of the joints or affections of any of the organs in which there was a tubercular deposit; that it had the power of producing infection, and that carbolic acid and other known disinfectants did not destroy this power; that the bacilli were often found in the sputa before a diagnosis of tuberculosis could be made from the physical signs. The greater the number of the bacilli the more active was the disease, and an accurate prognosis could be formed from the rapidity of the increase of the bacilli. In his cases the temperature of the body had not seemed to be obviously affected by the increased or diminished number of the bacilli present. Beautiful microscopic specimens of the bacillus of tuberculosis were shown and demonstrated by the reader.

THE USE AND ABUSE OF ERGOT.—This was the title of a paper read by Dr. G. L. WOODS, of Springfield. After an account of the physiological, toxicological, and therapeutical actions of

the drug, the writer recommended that it should never be given in obstetrical practice unless the uterus was empty, except to ward off an impending hæmorrhage. After delivery it was his custom to administer ergot for several days, as by its action involution of the uterus was aided.

Dr. WILLIAM A. DUNN, of Boston, followed with a paper on the same subject. The writer prefaced his paper by referring to the necessity of a more thorough, scientific, therapeutic study into the action of drugs. He then gave a description of the fungus, its history, the history of epidemics of ergotism, and a *résumé* of the physiological action of the drug as recorded by various observers. He recommended the use of ergot in various peripheral nervous diseases; but especially urged that it be given freely to "natural bleeders" before surgical operations, showing its value in this respect by reporting cases in which he had carried out this treatment with success; his rule being to give ergot for several days before the operation, and give a subcutaneous injection of ergotin twenty minutes before operating. The statement was made that ergot did no good in metrorrhagia, and that in menorrhagia it more often increased the trouble.

The main object of the paper was to discuss ergot from an obstetrical standpoint, however, and to emphasize the fact that the drug, even at the present day, was most carelessly used and abused in the ordinary routine practice, which stopped short of criminality only in that, in those cases in which death took place, the element of intention to kill was absent. The reader stated that he had attended between six and seven hundred labors. Formerly he gave ergot to multiparæ when the head was low, and after the membranes had ruptured, but he had met with so many cases of cyanosis, often requiring prolonged and anxious efforts for resuscitation, that he determined never again to give ergot till the uterus was empty. In the first stage of labor he never gave ergot, because tetanic uterine contraction was substituted for the normal rhythmical action of the organ, tending to prevent the proper dilatation of the os uteri, and to deprive the fetus of its blood-supply in consequence of compression of the uterine vessels.

In the second stage its exhibition was likely to produce the death of the fetus by pressure on the umbilical cord, and, after expulsion of the child, an hour-glass contraction of the uterus, with retained placenta, was liable to result.

In women of lax fiber, and with a roomy pelvis, ergot might be used, in small doses, when there was uterine inertia, if the forceps was not available, or if the obstetrician was timid in the use of the instrument; but it was better not to employ the drug, as success in a thousand cases would not compensate for the destruction of one infant, and many a certificate has been sent to the Board of Health in which "still-born" should be changed to "death from ergot." The rule resulting from his experience was to wait, as ergot was never absolutely necessary, unless we desired to control a post-partum hæmorrhage, or to anticipate one; and in either case large doses were not to be given unless the uterus was empty.

The danger to the mother from the use of ergot was, that it changed the character of the pains from the regular action to a continuous strain, and rupture either of the uterine body or of the cervix was liable to occur.

When ergot was given, the action of the child's heart should be watched, and with the first sign of failing strength the forceps should be applied to rescue the child from impending death from asphyxia.

The use of the drug was recommended to a limited degree in cases of placenta prævia, and in cases of abortion.

The afternoon session opened at three o'clock, ALFRED HOMER, M. D., of Watertown, President, in the chair.

THE CHEMISTRY AND PHYSIOLOGY OF GLYCOGEN.—Dr. J. W. WARREN, of Boston, read a paper on this subject, of such a nature that a condensed report can not be given that would either do it justice or be satisfactory to the reader.

PHLYCTENULAR DISEASES OF THE EYES.—Dr. O. F. WADSWORTH, of Boston, read a paper in which he stated that the affection was characterized by the eruption of vesicles or pustules on the conjunctiva or cornea, and was often attended by much apparent photophobia. The disease was familiar under the names of phlyctenular, pustular, scrofulous, and lymphatic ophthalmia, conjunctivitis, or keratitis, or herpes or eczema of the conjunctiva, or cornea, fascicular keratitis, or ulcer of the cornea.

It had been shown that affections of the conjunctiva and cornea make up half the sum of eye-diseases—Horner having found the cornea involved in 27.2 per cent., and the conjunctiva in 21.7 per cent.; and, according to the same authority, phlyctenular conjunctivitis and keratitis constituted more than half the diseases of these membranes in children. While the vast majority of those affected were young, adults were not wholly exempt, though with them the disease was comparatively rare. By the laity the malady was looked upon as a troublesome but innocent accompaniment of teething, or as a sequela of measles or other exanthem, and as not specially requiring treatment; consequently, "household remedies" were allowed to aggravate it.

The term "herpes," often applied, was a misnomer. There was no evidence that the eruption had any special connection with the sensory nerves, as was the case with herpes generally. Eczema, on the other hand, was a frequent accompaniment of phlyctenula, the ocular changes resembling in some degree those found in eczema. Yet there seemed hardly ground enough for adopting the title of eczema of the conjunctiva, as proposed by Horner.

The main characteristic was the eruption of vesicles or pustules. Its powers might be exhausted with the eruption of one phlyctenula, or successive crops might appear at irregular intervals; they might be situated on the conjunctiva, the cornea, or both, and might extend from one to the other. The duration of the individual efflorescence depended, in the main, upon its size and situation; on the cornea the course was slower than on the vascular conjunctiva.

A description was then given of the progress of the vesicles to ulceration. The loss of substance hardly extended deeper than the epithelial layer, but an infiltration leading to annular ulceration might occur. There was also a tendency to the formation of vessels, and, when this had continued for a long time, a sort of pannus was developed. The degree of injury to the eye as an organ of vision depended on the situation of the lesions. A considerable opacity near the circumference of the cornea might be of little moment in this respect, yet, without directly interfering with the entrance of light through the pupil, it might do harm by changing the proper curve of the cornea.

The most troublesome subjective symptom was photophobia. It seemed sometimes as if there were an effort to drag all the features—the forehead, the cheeks, and the lips—to one common center, and keep them over the eyes; yet it would be a mistake to suppose that the severity of the ocular affection could be accurately gauged by the photophobia.

In order to make a definite diagnosis or prognosis, inspection of the eye was absolutely necessary, and, to do this, the elevator of Desmarres should be used, otherwise injury to the eye was liable to occur in consequence of the patient's struggles.

The treatment might be divided into general and local. As the disease was "scrofulous" in the broad sense of the word, general treatment was of the greatest importance, and fresh

air, light, and food could not be overestimated. Even in the coldest weather out-door exercise was to be recommended. Blepharospasm was to be feared, not for itself, but for the prejudicial consequences it entailed. It was the irritation of the corneal nerves chiefly that excited this; therefore atropine should be used. Cold applications gave relief. All friction of the lids must be prevented. Excoriations about the eye might be treated with a solution of nitrate of silver or with zinc ointment. When the eruption was limited to the cornea, a borax collyrium was often all the local treatment needed. Calomel, dusted on till congestion disappeared, often prevented a relapse.

In general, astringents were to be avoided. The sluggish, deep infiltrations, whether at the edge of the cornea, or in a more central situation, showing little or no tendency to the formation of vessels, demanded, besides atropine, the application of hot fomentations at short intervals.

Many and various had been the remedies recommended to promote the absorption of corneal opacities left by this and other diseases, but the speaker's experience had been that nature produced the best results.

MINOR INJURIES OF THE SPINAL CORD.—A paper on this subject was read by Dr. B. H. HARTWELL, of Ayer. The writer spoke of the importance of paying close attention to all the symptoms in these minor injuries, not only from a pathological, but also from a medico-legal point of view. Often at first, when there was no sign of injury and the symptoms did not come on early, the patients were looked upon as malingerers, and treated as such. The objective and subjective symptoms should be carefully classified, and it should be remembered that they were often simulated. The statement of Hammond, that no verdict should be given unless the objective symptoms were present, was commented upon.

Nine cases of minor injury to the spinal cord were reported, in which the patients had been under observation for a long time. Of this number, three recovered, three were a long time under treatment and got no better, one got worse, one got better but not well, and one improved at first and then had a relapse. Though the symptoms were often late in coming on, the prognosis was generally favorable as to improvement, if not as to complete recovery.

The treatment consisted in relief from care, rest, and any position that was easy, the horizontal position often aggravating the symptoms. The medicinal treatment was ergot and belladonna, the latter being specially indicated if there was any vesical complication. The ergot was given in large doses, as was also the belladonna, the latter giving great relief when there was pain. Digitalis was recommended, but strychnine was contra-indicated at the start.

Warm sponges to the spine, counter-irritation, and dry cupping were also recommended.

PLUMBING APPLIANCES.—This was the subject of the closing paper of the day, by Professor T. M. CLARK, of the Institute of Technology. It gave a history of traps and the various appliances used by plumbers, and was illustrated by showing models and explaining their uses.

Wednesday—Second Day.

The session to-day, being the annual meeting proper, was called to order at nine o'clock, a. m., the President, Dr. Hosmer, in the chair.

The reports of the secretary and treasurer were read and accepted. After some further incidental business, the reading of communications was resumed.

RECENT CHANGES IN THE METHOD OF MEDICAL INSTRUCTION.—Dr. E. N. WHITTIER, of Boston, read a paper on this subject. A sketch of the old way of receiving a medical education was

given, the two-years' tickets for four months' tuition and a certificate being formerly all that was required. The value of the certificate could be seen when it was shown that the preceptor very seldom, if ever, asked his pupil a question concerning medicine, the student's time being spent in preparing drugs and in looking after the chores; and in the mean time, if a spare opportunity presented itself, he had the use of the doctor's books. This condition the speaker contrasted with the method of the present day, when four years' continuous work was expected, with, in many cases, an additional year in a hospital.

There was one faculty that was formerly trained which was now lost sight of in the anxiety to trace the science of medicine, to wit, individual observation. Dr. Jackson, in speaking of Dr. Holyoke, the first president of the Massachusetts Medical Society, said: "After a time he allowed me to walk with him," and this stimulation of the powers of observation was the great strength of the old system.

The object of the leading schools was not to graduate large classes, but to graduate well-qualified classes. In addition to extending the course to four years, as Harvard had done, it had been proposed to include in the preliminary examinations anatomy, chemistry, and physiology, so that laboratory investigation might be begun at once; and in the second year to have didactic instruction give place to clinical investigation. The art of observation must be cultivated, and the best way to accomplish this was to divide the classes into small sections, so that each pupil was brought into personal contact with the instructor.

The treatment in every case should be carefully marked out. If this were not done, but simply the history of the disease given, he who taught the art of healing was not a physician but a naturalist.

No class exercise was complete unless the blackboard was used, on which a display of the rational and physical signs was made, and a classification of symptoms given. The true secret in medical teaching was for the instructor to carefully do his work the first part of the year; to train the students in the correct way to investigate a case, and have each pupil do the work before the class the latter part of the year.

NEURASTHENIA.—Dr. J. S. GREEN, of Dorchester, read a paper in which he said that neurasthenia, or nerve-tire, was a disease of itself; it was not anæmia or hyperæmia, though either might be associated with it. The terms "nervous exhaustion" and "nervous exhaustibility" should not be confounded.

The chief cause of this condition was the mental activity which had its origin in our free schools and free press, stimulating one to put into action all his nerve power, leaving none in reserve. Thus the increase in rapid communication of knowledge, the ambition to lead in all we undertook, and the competition in life, brought with them cares and anxieties. The condition was not brought on by business or by study, but by competition and cramming; not by work, but by worry: and it was this that was sapping the energies of our people.

The Anglo-Saxons had been the first to feel the poison; they would be the first to find the antidote, and thus instruct the other slower races of people.

By our manner of living we no longer had girls; they became young ladies, then women, but skipped the period of girlhood. This was not so marked with boys; therefore we had more patients from the former than in the latter class.

Success in treatment lay in adjusting the patient to the situation, and regulating the expenditure of nerve force in the ratio of its production. Success could generally be promised, as there was a latent strength that could generally be drawn upon till the nervous centers recovered their former state. One great

point was, not to let the patient compare her condition with that of her neighbor.

Food, exercise, and rest, in the right proportion as each case required, were all that was necessary. Tonics were often useless and seldom necessary, provided the assimilation and digestion were properly performed. Sprinkling with cold water and friction were useful.

Uterine troubles might be ignored generally, though sometimes they required special treatment. Home was the best place for such patients, though a temporary change might do good.

THE ARTIFICIAL FEEDING OF INFANTS.—Dr. J. W. SPOONER, of Hingham, read a paper in which he said that when a mother could not nurse her child the question came up, What shall its food be? In the city a wet-nurse was recommended, but to those who lived in the country and did not want to feel as if they were living on a volcano, cow's milk was recommended.

The foods were divided into three kinds: 1. Milk. 2. Condensed milk. 3. Artificial foods.

As a result of his experiments, the reader had found that freshly drawn cow's milk was acid, but soon became alkaline. The conclusion he had drawn from his experience was, that artificial foods were not to be relied upon, though, of these, he had found "Mellen's food" to be the best. Condensed milk contained cane-sugar, and, though babies often grew fat upon it, yet when taken sick they lost strength rapidly.

The only objection to cow's milk was the hard curds that were apt to form, to soften which gelatin, arrow-root, and barley-water had been recommended; but he had found that Irish moss, boiled with water and then added to the milk, with a little lime-water, produced the best results. The reason for it was, that there was no starch in the mixture. Often he added cream.

THE EARLY SYMPTOMS OF GENERAL PARALYSIS OF THE INSANE.—Dr. W. B. GOLDSMITH, of Danvers, read a paper which contained a careful analysis of one hundred cases, and was of such a nature that a curtailed report can not satisfactorily be given.

THE ANNUAL DISCOURSE was given by Dr. AMOS H. JOHNSON, of Salem. He took for his theme the motto of the society, "*Natura duce*," and suggested that it should be changed to read, "*Ratione et natura ducibus*." He referred to the wonderful progress made in the study of astronomy and electricity during the last few years, and then turned to a consideration of the progress in the science of medicine, saying that it was chiefly the result of judgment and critical observation. He spoke of the danger of allowing patients to follow Nature as a guide, declaring that, in many instances, her advice proved fatal, and the physician must take the guidance of Nature's control over his patients. The indifference with which the presence of some contagious diseases was regarded was one of the moral influences which had to be met. The science of preventive medicine was of recent growth, but the facts acquired were of great value. He expressed a hope that the time would come when the State Board of Health would be relieved from fear of political influence, and attain its greatest usefulness. Nature could not be relied on to best interpret her suggestions to men; a careful study of the results obtained by the investigations of others was necessary; observation was not interpretation, to see was not to learn. A vote of thanks to Dr. Johnson was passed.

At one o'clock the members of the society walked to the Boston Skating Rink for the annual dinner. About eight hundred were present.

Dr. FRANCIS H. BROWN, of Boston, was anniversary chairman.

After dinner, speeches were made by Dr. Hosmer, Dr. Johnson, President Elliot, the Rev. E. A. Horton, and others.

Reports on the Progress of Medicine.

QUARTERLY REPORT ON MATERIA MEDICA, THERAPEUTICS, AND TOXICOLOGY.

No. XIII.

By GASPAR GRISWOLD, M.D.

TRANSFUSION OF BLOOD.—In a paper read before the Obstetrical Society of London ("Brit. Med. Jour.," Jan. 27, 1883), Mr. C. E. Jennings remarked that the nutritive value of defibrinated blood must be very small. But the value of transfusion depended primarily not upon the nutritive value of the substance injected so much as upon the dynamic effect of the operation. This latter could be procured more safely by the intravenous injection of saline solutions, and he was inclined to place more reliance upon this expedient in emergencies than upon the traditional operation of transfusion. In the course of the discussion that followed the reading of Mr. Jennings's paper, Dr. Ave-ling approved of the suggestion to rely mainly upon the intravenous injection of saline solutions; he further remarked that raising the legs of the patient above her head was a more efficient measure in syncope from loss of blood than was generally appreciated. Dr. Graily Hewitt thought the chief point in the paper was the attention directed to the dynamic effect of transfusion. This he believed to be very important. There was great difficulty in deciding when the operation was necessary. Patients might rally after post-partum hæmorrhage, and yet die some hours afterward without further loss of blood. J. Matthews Duncan regarded transfusion as merely a hopeful proceeding, demanding encouragement and study. Patients who survived it were often said to have been saved by it—a manifest mistake. Death had often been caused by it. Injections of plain water had been used with brilliant though only temporary results in cholera; he would like to see them fairly tried in hæmorrhage. The attempt to use blood introduced most of the dangers and difficulties of the operation, and these were increased by complicated apparatus. Dr. Herman said that, at the London Hospital, saline intravenous injections had been used in four cases of puerperal hæmorrhage, of which two recovered. In intravenous injection of pure water had been used once; the case had done well.

[The operation of transfusion is comparatively safe in animals. It has been done oftenest in dogs, which are not killed by the entrance of small quantities of air into the veins. In 1667, a dog, old and deaf, had his hearing improved, and was almost rejuvenated by transfusion of blood from a young animal. This caused great enthusiasm, and the operation was soon so frequently and rashly resorted to that a number of deaths resulted, and it was forbidden by law in Paris in 1668. In later days it has been revived, but with more moderation. The dangers of the operation are: the entrance of air into the veins, the presence of coagula in the blood injected, and the causation of phlebitis by the introduction of the cannula. It has never been considered safe to inject the blood of animals into the human subject, and it is a further drawback to the operation that it is rarely possible to obtain human blood in time to meet the requirements of the cases in which the operation is called for. The injection of even small quantities of fluid into a vein causes in the human subject such embarrassment of respiration and irregularity of heart-action that the operation must usually be suspended before more than three or four ounces have been introduced. The amount of blood, more or less impoverished by defibrination and filtration, which can be transfused at one time is, therefore, so insignificant compared with the hæmorrhage

which has prostrated the patient, that many authorities have felt inclined to attribute the resulting benefit rather to the dynamic influence of the operation upon arterial tension than to the red corpuscles introduced into the circulation. This is not the view of Prévost and Dumas, who asserted that the results of transfusion depended upon the corpuscles, and could not be obtained by the injection of serum from which they had been removed. Modern experience, however, is against these observers, and to-day several fluids have been injected to take the place of transfusion. The injection of milk has some advocates, being preferred to water and saline solutions, on the ground that it is nutritive. The milk, however, must be still warm from the cow, and not acid; and even then there is a danger of fatty embolism of the cerebral capillaries. It will be remembered that the diameter of many of the cerebral capillaries is very small—not more than the one six-thousandth of an inch; the fat globules of the milk are frequently not small enough to pass through, and the same train of symptoms is observed which occurs in lipæmia from fracture of long bones where the medullary fat gets into the circulation. These objections to the intravenous injection of milk have told against it, and it has not been so much employed of late. Saline solutions are probably the safest method of stimulating the failing powers; a solution whose saline constituents are the same as those of the blood may be injected with safety, and will probably accomplish all that could be gained by the more hazardous operation of transfusion. The author is not aware that the injection of defibrinated blood into the peritoneal cavity, as practiced by Ponfick, has ever been resorted to in this country. Compression of the femoral and brachial arteries, with the intravenous injection of two drachms of a fifty-per-cent. solution of ordinary aqua ammonia in water, is probably the most efficient means of re-suscitating those who are moribund from hæmorrhage. In all the instances in which the author has observed or heard of good results following the transfusion of defibrinated blood, each ounce of it contained three grains of carbonate of ammonium, ostensibly to prevent further coagulation. It has always appeared to the author that to this ammonia was largely due the temporary improvement which followed the operation. It is, perhaps, not superfluous to mention here that intravenous injection can not be performed, even with a hypodermic syringe, through the skin. The vein selected must be exposed by an incision through the skin before the needle can be introduced into it with accuracy and precision.]

THE INFLUENCE OF SULPHUROUS ACID IN ARRESTING PHTHISIS.—Herr Kircher, a pupil of Liebig, has been, during forty-four years, director of a factory in which a special form of manufacture is employed which involves the formation of sulphurous acid by the burning of sulphur. He maintains ("Lancet," Jan. 20, 1883) that none of his people have ever suffered from consumption. He recommends the following treatment in the case of tuberculous patients: They should be brought into a room in which one to two drachms of sulphur are burned every hour over a spirit lamp. At first, coughing, more or less aggravated, takes place; after eight or twelve days the bacteria disappear and cease to irritate the lung. To complete the cure, the patients should be brought into rooms which contain some aromatic vapors. [This raises the old question, Can bacteria be killed by disinfectants so little concentrated that they are not inimical to human life? All experiments made hitherto seem to show that they can not.]

DAMAGE TO THE HEART FROM THE INHALATION OF NITROUS OXIDE.—Dr. W. Otley (*ibid.*) records a case in which an existing valvular lesion was unfavorably influenced by the administration of nitrous oxide gas. The patient was a young woman who had suffered from rheumatic fever, and was left with a

slight mitral lesion. There was a faint murmur, at times hard to hear; the heart was but little enlarged, and there were no functional disturbances. On two occasions this patient took the gas, in order to escape the pain attending the extraction of teeth. The first time there was no trouble; the second time, a few days later, so much dyspnoea and cardiac irregularity were developed that the administration of the gas had to be suspended. Subsequently the patient suffered from palpitation and dyspnoea; the heart was found acting irregularly, and the murmur was very much louder. The heart now, for the first time, gave evidences of inadequacy. This case is interesting from its rarity, the gas having been given indiscriminately with surprisingly few accidents.

VENESECTOMY.—In an interesting paper on this subject (*ibid.*, Jan. 6, 13, 1883) Dr. W. H. Broadbent regrets that modern sentiment is so strongly against it, and proceeds to describe some conditions in which it is a most efficient remedy. In pulmonary congestion from pneumonia, severe bronchitis, or mitral stenosis, especially when attended with considerable dilatation of the right heart, as denoted by a systolic tricuspid murmur and venous pulse in the jugular, it affords immediate relief. In these cases venesection to even so small an amount as eight ounces causes the pulse to become slower, steadier, and fuller, and often relieves dyspnoea to a wonderful degree. The author does not believe that it is ever called for in aortic disease or in mitral regurgitation. A small venesection often temporarily relieves the distress from pressure effects in aortic aneurysm. In convulsions, associated with increased arterial tension, venesection is the best of all treatments; and this is equally true of convulsions uræmic and proceeding from other causes. In apoplexy, with great cyanosis and stertor, without failure of the pulse, venesection often does good and is without danger.

THE MULLEIN PLANT IN THE TREATMENT OF PULMONARY CONSUMPTION.—The *Verbascum thapsus*, or great mullein, has long been a popular remedy for phthisis in Ireland. It does not appear in the Pharmacopœia, but can be obtained at many good pharmacies. Old writers refer to it as a remedy for diarrhoea. It is prepared by boiling an ounce of the dried leaves in a pint of milk for ten minutes, and then straining. This strained fluid is given to the patient while still warm, sugar being added if desired. It is administered twice a day; the taste of the mixture is bland, mucilaginous, and not disagreeable. Dr. Quinlan ("Brit. Med. Jour.," Jan. 27, 1883) has tried the remedy in seven cases of phthisis in St. Vincent's Hospital, Dublin, with the following results: It soothed the cough to such an extent that patients who were taking it no longer needed their cough mixtures; and it unquestionably relieved the diarrhoea from which some were suffering. This last effect was not due merely to the boiled milk, as was proved by experiment. The mullein relieved dyspnoea, and was mildly stimulating and comforting. It had no effect upon night sweats, and did not seem to check loss of weight in febrile cases. The author is inclined to admit its value as a remedy in phthisis.

THE USE OF CALX SULPHURATA IN CUTANEOUS AND OTHER DISEASES.—Dr. Piffard ("Jour. of Cutaneous and Venereal Diseases," Jan., 1883) states that calx sulphurata (commonly called sulphide of calcium) was first used by the allopaths as an antidote to mercurial salivation. The homeopaths use it as a remedy against suppuration under the name *hepar sulphuris calcarea*. About ten years ago it was brought prominently into notice by Ringer as a remedy in *furunculosis*. He stated that it improved the quality of pus, hastened maturation, and prevented the formation of fresh boils. In carbuncles, also, Ringer believes it to be useful, melting the core to healthy pus, and so quickly expelling the dead and otherwise slow-separating tissue. The dose prescribed by him was $\frac{1}{10}$ grain every hour or two. Cane

has recommended the same remedy in acne. In acute pustular forms, the drug should be given in small doses, $\frac{1}{10}$ to $\frac{1}{8}$ of a grain; in more indolent forms, $\frac{1}{4}$ or even $\frac{1}{2}$ grain should be given until pustulation is induced. The remedy should then be stopped. Dr. Piffard has used the sulphide of calcium with good results in some cases of pustular eczema. He further mentions one case in which glycosuria disappeared while the patient was being treated with sulphide of calcium for eczema. This is of interest as supporting the assertion of Dr. N. C. Husted, that he himself was cured of glycosuria while taking sulphide of calcium for a boil. Dr. Husted has since reported other cases of recovery like his own. In strumous swellings of the upper lip and *ala nasi*, sulphide of calcium is an efficient remedy. As regards the physiological action of *calx sulphurata*, as the author prefers to call it, we know little or nothing; he inclines to the view, however, that it is a *resolvent* or *aplastic* of great energy, endowed with powers similar to those which have been attributed to mercury. It is probable that it exercises a beneficial influence over the progress of inflammatory exudations, chronic infiltrations, and even, perhaps, some forms of neoplasm.

THE PHYSIOLOGICAL ACTION OF CONVALLARIA MAJALIS.—After a series of experiments with convallaria majalis upon rabbits and frogs, Dr. Isaac Ott ("Arch. of Med.," Feb., 1883) formulates his conclusions as follows: 1. That convallaria increases the arterial tension greatly at the same time that the heart begins to beat more frequently; that the heart begins to fall before the tension. 2. The decrease of cardiac frequency is not due to excitation of the inhibitory apparatus, but rather to an action upon the heart itself, probably its muscular structure. 3. The rise of arterial tension is still present after section of the spinal cord high up; it is therefore mainly due to stimulation of other vaso-motor apparatus than the main monarchic vaso-motor center in the medulla. 4. The drug causes clonic spasms. If we compare the action of this drug with that of digitalis, we find that the slowing of the heart is due to different causes; with digitalis it is due to cardio-inhibitory excitation; with convallaria some other part of the heart is influenced. Digitalis does not primarily accelerate the heart; convallaria does. After section of the spinal cord, digitalis does not increase arterial tension; convallaria does. The great rise in arterial tension caused by convallaria would indicate its value in dropsies. Experiments on animals seem to show that it is a drug which should not be pushed to any great extent.

BLOODLETTING AND PERITONEAL TRANSFUSION IN THE TREATMENT OF RABIES.—Dr. Frigerio, in a paper upon hydrophobia ("Gazz. degli Ospitali," Feb. 25, 1883) details a *post-mortem* held in a case which terminated fatally without the convulsions having been in the least controlled by the heroic use of chloral. The author believes that the poison of rabies is a ferment which acts destructively upon the blood, and proposes as a remedy, which has not yet been tried, copious venesection followed by injection of blood into the peritoneal cavity (peritoneal transfusion). The author's argument is based upon the fact that some cures of hydrophobia treated by bloodletting have been reported, and upon his belief that the disease is caused by a fermentative process in the blood. On like grounds he might with equal propriety urge the same heroic treatment in almost any one of the essential fevers!

CHINOLINE IN THE TREATMENT OF DIPHTHERIA.—Dr. Seifert ("Berl. klin. Woch.," No. 22, 1883) describes a series of cases, slight and severe, in both children and adults, which were treated with this remedy. The only death occurred in the case of a child a year and a half old, sickly with constitutional syphilis. Seifert employs a five-per-cent. solution of pure chinoline in equal parts of alcohol and water as a local application, and a one-fifth-per-cent. solution in water, with a little spirit

and peppermint, as a gargle. The pure chinoline is less disagreeable than the tartrate used hitherto. The local applications are made as often as once in four hours in severe cases; they are followed at first by considerable smarting and burning, but this may be relieved by taking a swallow of water. The throat soon after feels much easier, and the power of deglutition is rapidly restored. The patches rapidly separate, and the glandular swelling soon subsides. The author is a strong believer in the local nature of diphtheria, and employs no further treatment beyond an ice cravat in bad cases.

ADONIS VERNALIS IN RENAL AND CARDIAC DROPSIES.—Dr. Bubnow, of St. Petersburg ("Lancet," Jan. 6, 1883), describes *Adonis vernalis*, a popular remedy in Russia for renal and cardiac dropsies. Under its influence, in cases of dropsy, the cardiac contractions increased in force and diminished in frequency, the urine was augmented and no longer contained casts or albumin. Experiments on both cold-blooded and warm-blooded animals with different preparations of adonis (infusions, and both aqueous and alcoholic extracts) showed that its action is to stimulate both the motor ganglia and the inhibitory apparatus of the heart, and to raise arterial tension. Dr. Bubnow prefers adonis to digitalis, and states that, like *Convallaria maialis*, it has no cumulative action. A glucoside, *adonidin*, containing the active principle of adonis, has been isolated by Cervello ("Archiv für exp. Path. und Pharmacol.," 1882, p. 335). The effects of *adonidin* are very similar to those of digitalin. It is not improbable that the same similarity may prove to exist between adonis and digitalis as exists between hyoscyamus and belladonna.

Miscellany.

THE USE OF ANÆSTHETICS DURING LABOR.—In a recent number of the "British Medical Journal" Dr. T. D. Savill indicates what he believes to be the main precautions, the observations of which would render the use of chloroform perfectly justifiable. 1. There are certain women who have a tendency to flood at every confinement, and others in whom there seems an already too great relaxation of fiber—weak anemic females in their eighth or tenth confinement; and to these it would be unadvisable to give chloroform, except for necessity. Happily, it is not these women who suffer the most pain, but rather those strong, healthy primiparae whose pelvis and general build approximate to the masculine type. 2. We should not give it when labor is complicated with severe vomiting, or with acute heart or lung disease, unless there is imperative call for it. 3. It should not be given to the full extent, except for operation, convulsions, or spasm of the cervix; and then it is necessary that one person should devote his entire attention to it. 4. The inhalation should be stopped directly we find the pulse becoming very weak, or the respiration irregular. 5. Anything which makes us suspect a fatty or embolized cardiac wall should make us cautious in the use of chloroform. Here, as in cases other than those of labor, it is not the most extensive valvular disease (so long as it is attended with compensating hypertrophy), but the atrophied or degenerate wall that constitutes the source of danger. Unfortunately, the signs of these conditions are subtle and uncertain. Fatty heart may be suspected by an exceedingly feeble cardiac impulse, combined with an almost inaudible first sound; or attacks of dyspnoea, vertigo, and syncope, in the absence of anæmia or valvular lesion; or the copious deposit of fat in other parts of the body, and the occurrence of dropsy without adequate cause. A dilated heart may be suspected by increased area of precordial dullness, combined with epigastric and venous pulsation, and a want of correspondence between the violence of the cardiac impulse and the strength of the pulse. Pericardial adhesions also form a great source of danger. They may be suspected when the heart's apex is fixed above its normal position, and does not shift

with respiration; or when there is depression instead of protrusion of intercostal spaces over the position of the apex, giving a wavy character to the cardiac impulse. 6. In all cases we should take particular care to prevent the occurrence of hæmorrhage, a too high or giving a full dose of ergot when the head reaches the perineum, by ceasing the chloroform immediately it is born, and by rousing the patient from her lethargy as soon as possible.

A SPINA BIFIDA PRESENTATION.—Mr. Charles Penttilä, M. R. C. S., of Winchester, writes to the "British Medical Journal": On April 13, 1883, I was called by the midwife to attend Mrs. B., who was in labor with her fourth child. Labor commenced at 2 p. m. of the previous day; the pains had been very severe until 10 p. m., but after that time became few and far between, and of very late onset. When I saw Mrs. B., the pains appeared to be moderately strong but of short duration. There had been nothing abnormal in her previous confinements. On making an examination, it was with great difficulty that I could reach the os, which I found nearly fully dilated; its margins were rather flaccid, and during a "pain" the presenting portion of the child exerted no pressure on them whatever. From what I could feel of the presentation, I at first thought I had a face to deal with, there being something which very closely resembled the well-defined margins of the orbits; beyond this I thought I felt the nose, and still a little farther on my fingers slipped into what I at once took to be a mouth, only it was somewhat jagged inside, as though it were lined with fully developed teeth; I then came across a hand. I passed my hand into the vagina to make a more thorough examination, satisfied myself it was not the face, and at the same time could feel the considerable smooth outline of a child's hip, but, owing to the irregularities, I was unable to tell clearly what the arrangement of parts could be, and decided to call in my friend and colleague, Mr. William Cox. We came to the conclusion that it was no face, but the lumbar region that presented, and therefore decided to turn. This was accomplished in the usual way, and the feet brought down, only slight difficulty being experienced until the head was being extracted, but, with my left forefinger in the child's mouth and my right hand on its occiput, this was soon overcome. The placenta soon followed, and the mother made a good and rapid recovery. The child, a female, appeared to have been dead about twelve hours, and was fully developed. The head was somewhat hydrocephalic. On further examining the body, we found the cause of our not being able to clearly diagnose the presentation to be a large spina bifida situated in the middle of the lumbar region, and very much resembling to the touch the part for which I had at first mistaken it. This case struck me as being very interesting in showing how a diseased condition of a fetus may confound the diagnosis of the accoucheur.

SYPHILIS IN THE NINTH CENTURY.—"Between the years A. D. 800 and 810," says the "British Medical Journal," an emperor of Japan commanded his court physicians, Abemamas and Idzumo Kirotsada, to collect in one volume all extant records of native medicine and surgery. A manuscript copy of this work, for centuries forgotten, although the facts of its origin were recorded in Japanese history, was found in 1827 by a priest, in a provincial Buddhist temple. Dr. Scheube, of Leipzig, has recently examined this work, and, in an article published in a recent number of Virchow's "Archiv," has shown its undoubted authenticity and its high value from a purely scientific point of view. It was written long before Chinese ideas had penetrated into Japan and influenced native practitioners. The most interesting passages are descriptions of local and general affections, which clearly prove that syphilis, and several allied disorders, were well known to the ancient Japanese. Chancreoid and phagedenic chancre are clearly described, as well as a 'swelling on the penis, of the size of a millet-seed,' followed by eruptions, feverishness, pains in the bones and head, blindness, swelling of the testicles, and other very familiar symptoms. These were observed to continue for many years. The pas-sages of this work, called the Daidori Thiu-ho, which relate to the treatment of these symptoms have not yet been translated into English. Heretofore, it appears to have been used, and without much success, as a guide to treatment was introduced at a comparatively recent date, from Europe. The ancient Japanese surgeons do not appear to have recognized the

venerable origin of the disease which they describe, although the Daidorui distinctly traces all the secondary symptoms to 'the poison from the affected organ.' "

OIL OF TURPENTINE smeared upon the hands has been found an excellent preventive of septic infection in autopsies.

PRECAUTIONS AGAINST THE CONTAGIOUS DISEASES OF DOMESTIC ANIMALS.—By a recent amendment of the New Jersey statutes, all persons, who shall own or have in their possession any poultry or animals of any kind which may come to their death from any contagious disease, shall within twenty-four hours after such death bury the carcass in not less than two feet of earth.—*Sanitary News.*

THE AMERICAN NEUROLOGICAL ASSOCIATION.—The ninth annual meeting will be held at the Academy of Medicine, 12 West Thirty-first Street, New York, on Wednesday, Thursday, and Friday of next week. We are asked to give notice that members of the profession are invited to attend the sessions.

The programme is as follows:

WEDNESDAY, JUNE 20TH.—*Afternoon Session at 2.30 o'clock.*—Roll-call, and introduction of the president-elect, by the secretary. Address by the president, Dr. Robert T. Edes. Reports of Council, of secretary, and treasurer. Scientific communications: (1) Dr. W. J. Morton, of New York—Neuritis following Dislocation. (2) Dr. C. L. Dana, of New York—Note on Hydrobromic Acid as a Substitute for the Bromides. (3) Dr. T. A. McBride, of New York—Migraine; its Pathology and Localization.

Evening Session at 8.30 o'clock.—Scientific communications: (4) Dr. C. K. Mills, of Philadelphia—A Case of Locomotor Ataxia terminating as General Paralysis of the Insane. (5) Dr. E. C. Spitzka, of New York—Remarks on the Alleged Relation of Speech Disturbance and the Patellar Tendon Reflex in Parietic Dementia.

THURSDAY, JUNE 21ST.—*Afternoon Session at 2.30 o'clock.*—Scientific communications: (6) Dr. Robert T. Edes, of Boston—The Excretion of Phosphites and Phosphorus as Connected with Mental Labor. (7) Dr. R. W. Amidon, of New York—A Case of Tetanoid Pseudo-Paraplegia, of interest from an Etiological and Pathological Point of View. (8) Dr. W. J. Morton, of New York—An Apparatus for Treating Scrivener's Palsy. (9) Dr. E. C. Seguin, of New York—The Insane of Spain and their Asylums. A communication by letter.

There will be no evening session on this day, and in lieu thereof Dr. R. W. Amidon will give a reception and dinner to the president at Delmonico's at 7 P. M. The members of the association are hereby respectfully invited to attend.

FRIDAY, JUNE 22D.—*Afternoon Session at 2.30 o'clock.*—Scientific communications: (10) Dr. Burt G. Wilder, of Ithaca—The Brain of the Cat, Lacking the Callosum. On the Alleged Homology of the Carnivora Fissura Cruciate with the Primatal Fissura Centralis. (11) Dr. E. C. Spitzka, of New York—Lesion of the Stratum Intermedium, with Remarks on the Anatomy and Physiology of that Tract, Illustrated by Specimens. (12) Dr. W. J. Morton, of New York—On the Treatment of Migraine.

Evening Session at 8.30 o'clock.—Scientific communications: (13) Dr. C. L. Dana, of New York—Note on the Treatment of Chorea by the Sedative Galvanization of the Brain. (14) Dr. Burt G. Wilder, of Ithaca—On the Removal and Preservation of the Human Brain. On Some Points in the Anatomy of the Human Brain.

THE NEW HAMPSHIRE STATE MEDICAL SOCIETY.—At the ninety-third annual meeting, to be held in Concord on the 19th inst., it is expected that papers will be read by Dr. Hatch, of Wilton; Dr. Stillings and Dr. Watson, of Concord; Dr. Smith, of Hanover; Dr. Blaisdell, of Contoocook; Dr. Pray and Dr. Stackpole, of Dover; and Dr. Adams, of Manchester.

THE LONG ISLAND COLLEGE HOSPITAL ALUMNI ASSOCIATION.—The third annual dinner will be given at the Brighton Beach Hotel, on Monday, the 18th inst., at 5.30 P. M.

THE MINNESOTA COLLEGE HOSPITAL LECTURES ON HYGIENE.—We understand that Dr. George H. Robé, Professor of Dermatology and Hygiene in the College of Physicians and Surgeons of Baltimore, has

been engaged to give a course of lectures on hygiene at the Minnesota College Hospital, occupying one hour daily from October 22d to November 3d, inclusive. We congratulate the faculty on their enterprise and on the wisdom shown in the choice of Dr. Robé. The lectures will be open to the profession of the State.

THE PENNSYLVANIA ANATOMY BILL has become a law, practically with but little change from the original draft.

THE NEW HEALTH COMMISSIONER.—Since our last issue the Mayor has nominated General Alexander Shaler to succeed Professor Chandler in the Board of Health, and on Wednesday the nomination was confirmed by the Board of Aldermen.

THE TEWESBURY ALMSHOUSE.—Dr. C. Irving Fisher has been appointed resident physician.

WOMEN PHYSICIANS IN MASSACHUSETTS.—At the recent meeting of the Massachusetts Medical Society there was one lady physician present. Women as yet are not admitted to the rights and privileges of the society, but it appears that the majority of the male physicians of the State are willing that women should be recognized. In a circular recently sent out to members, among other questions, this one was asked: "Do you favor the admission of women to the society on the same terms with the men?" Of a total membership of 1,343, 1,132 answered the question, of whom 706 said "yes," 400 "no," while 23 were indifferent. Three hundred and thirty-six physicians stated that they had consulted with female practitioners, 684, out of 1,020 who answered the query of the circular, said they had not, but 931 expressed a willingness to consult with them, as against 146 who, on account of their sex, would not.

BODY-SNATCHING IN SYRACUSE.—Several persons are said to have been indicted recently in Syracuse, N. Y., for complicity in the desecration of a grave. The charge is that a body was exhumed and taken to the Syracuse University Medical College. A recent graduate and a member of the graduating class are among the accused. We trust that they will be shown to be innocent.

DEATH OF DR. NOAH C. LEVINGS.—Dr. Levings died on Sunday, the 10th inst., at the age of fifty-nine years. He was a graduate of the Medical Department of the University of the City of New York, class of 1844, and a member of the Medical Society of the County of New York.

ARMY INTELLIGENCE.—*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from June 2, 1885, to June 9, 1885.*—ALEXANDER, CHARLES T., Major and Surgeon. So much of Par. 6, S. O. 82, A. G. O., April 10, 1883, amended to direct that he be relieved from duty at the United States Military Academy, West Point, N. Y., October 1, 1883. Par. 7, S. O. 125, A. G. O., June 1, 1883. —McKEE, J. C., Major and Surgeon. Assigned to duty as Post Surgeon, Presidio of San Francisco, Cal. Par. 2, S. O. 56, Department of California, May 25, 1883. —DE LOFFRE, A. A., Captain and Assistant Surgeon. To proceed to Macdon Barracks, N. Y., and report to the Post Commander for duty. Par. 2, S. O. 98, Department of the East, June 8, 1883.

SOCIETY MEETINGS FOR THE COMING WEEK.—*Monday, June 18th:* Medico-Chirurgical Society of German Physicians. *Tuesday, June 19th:* New Hampshire State Medical Society (Concord—annual); New York Academy of Medicine (Section in Medicine); Medical Society of the County of Kings, N. Y.; Medical Society of the County of Westchester, N. Y. (White Plains—annual); Ogdensburg Medical Association. *Wednesday, June 20th:* American Neurological Association (New York—annual—first day); Medical Society of the County of New York (Columbia Minor); Medical Society of the County of Alleghany, N. Y. (annual); New Jersey Academy of Medicine (Newark). *Thursday, June 21st:* American Neurological Association (second day). *Friday, June 22d:* American Neurological Association (third day); New York Clinical Society (private); New York Society of German Physicians (private). *Saturday, June 23d:* New York Medical and Surgical Society (private).

Lectures and Addresses.

LECTURES ON
HUMAN AUTOMATISM.

DELIVERED AT THE LOWELL INSTITUTE, BOSTON.

By WILLIAM B. CARPENTER, M.D., LL.D., F.R.S., ETC.

LECTURE V.

(Continued from page 621.)

Passing by, for want of time, many other phenomena of binocular vision which have a very direct bearing on our present inquiry, I shall call your attention to a comparison between our visual perceptions of *near* objects and the perceptive judgments which we form of the sizes and distances of *remote* objects, which have an entirely different basis. In directing our gaze to any distant object, the axes of our eyes are virtually parallel; so that we gain no information from the conjoint use of both which the use of either eye separately is not competent to afford. Hence, we can not, even across a room, distinguish with certainty (unless we move the *head* sufficiently to produce a change of parallax) between an actual solid body and a picture of that body so executed as to convey the effect of solidity by its perspective and its *chiaroscuro*. Probably all of you have had this experience, either in regard to a well-painted scene in a theatre,* or in looking at paintings intended to imitate *reliefs*, which they sometimes do with marvelous deceptiveness.

But some of you may have noticed the same effect as produced by paintings—still more by photographs—when looked at from a short distance with *one* eye; and nothing better tests the truthfulness of a perspective representation of different distances than this mode of viewing it. For the parts either of a landscape or of an architectural interior then take up (as it were) their respective positions—provided that the pictorial representation of them is accurate—so as to give a much greater *reality* to the scene than when it is viewed with the two eyes conjointly; and the effect becomes more and more vivid the longer we look at the picture. Now, this fact may seem in contradiction to what I have been saying of the peculiar value of *binocular* vision; but I shall show you that it is in complete accordance with all that has gone before. When you look with both eyes at a photograph that is within eighteen inches or two feet of them, you are *forced* to see that it is a flat surface, unless it represents an object in very low relief. (I have one or two photographs of *reliefs* in which the relief is so low that, when I look at them with both eyes at arm's length, I am not altogether sure perceptually, though I am intellectually—as *knowing* it to be so—that their surface is flat.) When, however, you close one eye, you are no longer

obliged to see that the surface is flat; for you can not distinguish the relative distances of different parts without the information supplied by the convergence of the optic axes. Under these circumstances, the suggestions given by the perspective representation, and by the distribution of the lights and shadows, exert their full effect; and I have several photographs as to which, when they are properly lighted (for much depends on the correspondence in direction between the light under which the photograph is viewed and that under which it was taken, so that the shadows of the picture may be such as would be given by a real *relievo* similarly viewed), I would defy almost any one who did not know that he was looking at a flat surface to distinguish them from the actually projecting solids whose aspects they represent.* And, even when such a picture is intellectually known to be a flat surface, we find it as difficult to *see* it flat as to see flatness in the stereoscopic image.

In the one case, as in the other, the perceptive judgment is formed automatically, upon the basis of the *accordance of the sensorial image with that of the actual solids which the mind has trained itself to receive and interpret*; and the reason why photographs usually give this effect better than paintings is because of their greater truthfulness as representations of the appearance of the objects suited to them at the particular moment at which each is taken.

We must now pass from the subject of intuitional perception to that of the automatic succession of the higher intellectual processes; and of these, I think, it will be only necessary for me to bring before you a few illustrations, because every psychologist is perfectly aware that there are uniformities of succession—expressed in the term “laws of thought”—which uniformities constitute the purely automatic operation of (we may say) our brains or our minds, according as we choose to represent the fact in terms of matter or in terms of mind. Some of these uniformities seem to be pretty constant through the whole human race, whereas others will depend upon the particular direction which is taken by the individual mind, in virtue of its original constitution, the educational training it has received, and the special knowledge it has acquired. If we leave our mind free to be acted upon by surrounding impressions only, the successions of thought and feeling may be traced to the succession of those impressions, as we see to be the case with young children; but, on the other hand, when we direct our minds determinately to a particular object of contemplation—whether this be purely intellectual, or excites our artistic and poetic feelings, or acts on our emotional nature—in moving along any of these lines our “training” very much determines the particular ideas and feelings which will successively present themselves. On the other hand, it is assuredly in the power of the *Ego* to fix his attention on the particular mental states which he wishes to follow up; and, by intensifying these, to exclude the rest from his consciousness of this determinate fixation of the atten-

* The completeness of the illusory effect of the dramatic views formerly exhibited in Paris and London was in great measure due to the exactness with which their perspective and *chiaroscuro* were rendered, on the basis of sun-pictures obtained by the Daguerreotype process.

* The best way of making this experiment is to close the photograph to be viewed through a conical tube having a circular aperture at its farther end of such a size and shape as to exclude the “moment” of the photograph, and limit the vision to the picture itself.

tion upon purely intellectual conceptions. We have an example in the answer which Newton is said to have given to some one who asked him how he had arrived at his wonderful discoveries—"by always thinking about them." And the great naturalist, so recently lost to us, who has left an impress on the thought of the age not less strong or far-reaching than that of Newton, was, in like manner, always pondering over the verification of his grand ideas. Turning from the philosopher to the poet, we find Wordsworth clearly expressing the same truth in the preface to his "Lyrical Ballads," in which he gives an account of his own mental processes. He states that he has made it his habit to fix his attention upon the various aspects of nature, or of human nature, until his feelings have (so to speak) overflowed in poetry; and he says, I think very truly, that all the best poetry, that which is most effective in its appeal to the poetical consciousness of other minds, is that which is the result of this spontaneous overflow. This is clearly the case in musical creation. Every one who has read the life of Mozart will remember that his wonderful musical faculty—trained and directed as it had been, in all the musical learning of that time, by the careful direction given by his father to his study of it—enabled him to produce appropriate music, as it were, "at call." It was simply necessary for him, when he had a work to compose, to think a little about the plan which he should follow—if, for instance, it should be an opera, to settle what should be recitative and what song, what should be solo, duet, trio, quartette, chorus, and so on—for his ideas to flow forth and shape themselves into regular musical forms, so as finally to evolve the complete work.

Of this *selective attention* to particular trains of thought, whose succession has been strictly determined by previous habit, we have a typical example in the higher forms of mathematical research. A mathematician, sitting down to apply his trained ability to the investigation of some particular class of phenomena not as yet brought within the scope of mathematical reasoning, sets himself to consider which among the various methods open to his choice is the one most likely to lead him to the desired result. Choosing, for example, the method of quaternions, or the differential calculus, he brings this to bear upon the problem to be solved, fixing his attention continuously upon it until he either sees his way to the manner of proceeding, or, finding himself unable to make further progress on that line, tries another method. When he has once divined the *mode* in which the problem is to be attacked, the working out of the solution is a matter of simple deductive reasoning. It is well known that among mathematicians of the highest ability there is a very considerable difference in their particular capacity for the solution of puzzling problems. The position of senior wrangler at (our) Cambridge has been often gained by a certain special ability of this kind, which has placed its possessor above a competitor who was his superior in the power of applying the highest mathematics to physical inquiry. This last has been the leading subject of examination for another honor known as the "Smith's prize," and it has frequently happened that the senior wrangler has come out second Smith's prize man, while the

second wrangler has come out first Smith's prize man, showing the existence of two different qualities of mind—the one the purely intellectual capacity to apply mathematical reasoning to the conditions of a known case, the other a sort of divining power more akin to the imagination, which enables its possessor to discern the direction in which the solution is to be obtained. It is the man of *genius* who extends the boundaries of his science, while the man of *talent* utilizes all available material for the building up (so to speak) of his ideal cosmos. But each works by his power of *fixing his attention*—in the one case on the object to be attained (as when Kepler was seeking for the ideal harmonies of the planetary motions), and, on the other, on the successive stages of his constructive work.

Take, again, the phenomena of memory, which are, I think, the most instructive, while the most familiar, of all. We desire to recollect something which we have not at the moment before our minds; we wish to call up, for example, the personality of some one whom we have met, and whose face we recognize without being able to say who he is—that is to say, to connect him with any name or image of his character with which our minds have been previously impressed. We say to ourselves, "We know we ought to recognize such a person," and yet we can not recall the ideational conception that we ought to connect with the sensorial image of him, the association of the former with the latter not having become strong enough by repetition to call it up, as has happened to myself very frequently—indeed, in the last month. We know that we have been introduced to him, we have heard a good deal about him, we have, perhaps, had conversation with him, and yet neither will the name present itself, nor that general recognition of *personality*; that is to say, the concrete resultant of all that has come to our knowledge about him, to which the mention of his name ordinarily leads us. Or, again, I have in my mind some statement of a scientific or historical fact, or, it may be, a line of poetry, or a passage of prose, the original source of which I am sure I have known, and would fain recall. In either of these cases we fix our attention upon these ideas, and spontaneous successions of ideas, which lie (so to speak) in the direction of what we seek, and endeavor, by following up one track after another, to find the idea of which we are sure that we have the "physical trace" only waiting to be got at. And if, after an unsuccessful search, we give it up and let our thoughts take an entirely different direction, it continually happens (perhaps after a night's rest) that the lost idea presents itself to our minds without our being conscious of anything that brought it there. But further experience teaches that this spontaneous reproduction is more likely to occur if, after we have thought of all that seems likely to lead us toward the object of our search, we give up our quest, instead of worrying and fatiguing ourselves by unavailing persistence in it. I remember that when—many years ago—I was talking over this subject with my late friend, Sir Henry Holland (of whose valuable essays on psychological subjects I have already made mention), he read me an interesting letter he had just received from Mr. Edward Everett, with whom he had been very intimate when he

was your minister in London. Mr. Everett, as you know, soon after his return home, became president of Harvard University; and he had written to Sir Henry of a difficulty which was continually occurring to him. Falling, he said, into his old literary associations, he was often desirous of bringing to mind the authorship and context of some passage that was familiar to him, and was much vexed at his inability to do so. In reply, Sir Henry had advised him to do just what I should myself have suggested—namely, not to distress himself at the unreadiness of his memory, but to look upon it as having only rusted from disuse; and, after thinking over all the probable originals of the passage he wanted to trace out, to leave the matter alone, with the expectation that the answer would soon come of itself. And the letter which Sir Henry read to me from Mr. Everett was one of warm gratitude for the recommendation, which (he said) he had frequently put in practice with the most satisfactory results.

Now, every one of you, I doubt not, has had experience of this kind in one form or another. No thoughtful person can fail to recognize the fact that these forgotten reminiscences, buried (as it were) somewhere down in the cellars of our minds, where we can not find them by looking for them, turn up of themselves after we have given up the search, the light we have let in upon them having produced their revival, not immediately, but by a train of operations which our search has started. And here we have an instance of pure automatism, proceeding along tracks previously laid down, but first put in action by volitional direction.

This form of automatism, which I believe to have a large share in our mental life, is what I have designated "unconscious cerebration." I do not attach any importance to the term, provided the fact be recognized that a great deal of what we commonly rank as *mental* work is done *unconsciously*, and, therefore, *automatically*. This has been fully admitted by the purest metaphysicians, Sir William Hamilton for example; and the "philosophy of the unconscious" enters largely into modern German psychology. As English writers, on the other hand, have been accustomed to limit *mental* action to that of which we are *conscious*, and to treat everything *beneath our consciousness* as a function of our bodily organism, I based my designation upon what—as a physiologist—I regard as the material instrument which furnishes the mechanism of the operation; and the term has met with wide acceptance among those modern psychologists who perceive that there is such a constant interaction between the *physical* and the *psychical* in man's composite nature that neither can be fully discussed to the exclusion of the other.*

I believe it to be in this manner that the "integration of our experiences" is effected—of which I have already spoken as one of the most important and most constant of our psychical processes—what is true of our experiences as to external objects being equally true of our ideational and emotional experiences. Our general conception of almost any subject is built up on a foundation much wider than our conscious thought of it; and our desires and aversions, our likes and dislikes, are generally the resultants of a number of separate impressions which we have not knowingly worked up into distinct judgments. And we often experience a "change of mind" as to what is probably true or untrue, or as to a personal like or dislike, by an unconscious remodeling (as it were) of our fabric of thought. And I hold, with your own Dr. O. Wendell Holmes (whose short essay on "The Mechanism of Thought and Morals" is full of such "resultants"), that creative genius—whether that of the mathematician or the mechanical inventor, the musician or the painter, the sculptor or the poet—always works in this fashion; his original gift, trained by judicious guidance and improved by the teachings of experience, evolving its ideal conceptions in their appropriate forms, as resultants of long successions of processes that have gone on unconsciously to himself, whether in his cerebrum or in his under-soul, seems to me a matter of terminology only.

(To be concluded.)

Original Communications.

ON THE LOCAL USE OF ANTISEPTICS AFTER LABOR AND ABORTION.*

By W. GILL WYLLIE, M. D.,

PROFESSOR OF GYNECOLOGY IN THE NEW YORK POLYCLINIC; GYNECOLOGIST
TO BELLEVUE HOSPITAL.

In 1870 and 1871, while interne at Bellevue Hospital, I saw much of septicæmia in surgical cases, and something, also, of septicæmia in puerperal cases. Under the teachings of Dr. James R. Wood, I became a believer in carbolic acid, and, by its free use, and by the abolition of all sponges, old rubber cloths, etc., I served a month in the lying-in wards and delivered thirty-six women without a case of puerperal fever. All the women had some rise of temperature, but none over 102° F. at any time. In 1872 I saw Mr. Lister at work in his wards in the infirmary at Edinburgh, became a convert to Listerism, brought back with me the material for carrying out his method, and have used it in private practice since then. I have also used it in all cases of labor, of course modified, but still following the principles and teaching of Lister. In some fifty odd cases, not one had puerperal fever, and, excepting three cases with cracked nipples, only one had a rise of temperature above 100°. It is true that there is nothing unusual in delivering

as being as truly the products of those changes as our sensations are of their physical antecedents.

* Read before the Medical Society of the County of New York, May 28, 1883.

* Dr. Alexander Winchell ("Science and Religion," pp. 125 and 231 of English reprint) appears unable to perceive how entirely consistent is the doctrine I advocate with the fact universally admitted—save by those who hold the doctrine of the complete *dividing* of man's nature, with its corollary of "pre-established harmonies"—that a certain physical change in our sensorial apparatus is the *cause* of that psychical state which we feel as a sensation (see Lecture I, my position being simply that certain physical changes in the cerebrum may take place without our consciousness, which, when translated into consciousness, become ideas; and that the resultant ideas may be regarded

fifty women among the better classes without a death or any indications of septicæmia, but to have case after case go through all the stages without any perceptible rise of temperature, no so-called milk fever, and without even the well-known odor of the lying-in room, at least repaid me for my care.

The method is very simple:

1. I make it a rule to examine locally every case some weeks before labor, and to have a trained nurse on hand several days before labor is expected. If there is a leucorrhœa, warm vaginal douches, 1-to-50 sol. acid. carbol., are given twice a day, and in all cases, as soon as the first symptoms of labor begin, the vagina and vulva are thoroughly washed with a solution of carbolic acid.

2. The room is prepared by removing all useless and old stuffy furniture, etc., and everything left is disinfected with a spray of carbolic acid solution; the nurse sees that a large supply of napkins and bed linen is on hand, all of which are carbolized with the spray immediately before being used. The linen is changed every day, and two sets of blankets are aired and used alternately. All instruments and hands used are first washed in sol. (1 to 20) acid. carbol.

3. When labor begins, the spray is set going, and after labor every napkin is carbolized, or carbolized muslin or oakum is used to catch the lochia, and changed, according to the discharge, every hour or two, night and day.

4. Just after labor the parts are thoroughly washed with a 1-to-30 sol. acid. carbol., and vaginal douches are given from two to four times a day. This is kept up faithfully for six or ten days, as required.

5. The test of all this is that at no time should one be able to recognize by the smell an odor such as usually characterizes a lying-in room.

For cases of abortion I have tried to carry out the same practice, and all cases that I attended from the beginning have escaped without fever. Within the past three years I have attended four well-marked cases of septicæmia after abortion.

The following is the history of one of these, taken from a careful record made at the time:

Mrs. M., aged thirty, a vigorous and healthy American, the mother of two children, came to the city from Pennsylvania to be operated upon for laceration of the cervix uteri. The operation was done by a professor of gynecology in November, 1878. In February, 1879, I saw her and treated her for acute cervicitis and endometritis, which she attributed to the operation. The cervix was impassable to the smallest sound. After opening the cervix, in about six weeks I sent her home cured. She was quite well until October next, when she failed to menstruate, and had some symptoms of pregnancy. She consulted a physician: he told her that the uterus was enlarged and inflamed, and needed treatment. Several sponge tents were introduced, with the view of opening the cervix, but the first one was forced out in less than an hour, and the second gave so much pain that she refused to have anything more done, and took the night train for New York.

The next morning, October 27th, while at breakfast in her hotel, after a few pains a profuse and sudden hemorrhage came on, and a large amount of blood was lost before she reached her room. Dr. G., of the hotel, was called, and at once introduced a tampon of cotton pledgets, and was obliged to renew it in

four or five hours. I saw her at 8 P. M.; she was very thirsty, gave evidence of having lost much blood, had great pain, and was flowing freely. I removed the tampon and put in another. At 10.30 P. M. Dr. Sims saw her with me, and agreed with me that an abortion was imminent. A very firm tampon was again introduced, and sufficient morphine was given to keep her quiet for the night.

October 28th.—The next morning the tampon was removed, and a watery discharge escaped; at 4 P. M. the cervix was dilated to the size of a silver quarter-dollar; as there was no loss of blood, and only slight pain, nothing more was done.

29th, 10 A. M.—On account of increased pains and renewal of the hemorrhage, it was decided, after consultation, to put in a sponge tent. At 4 P. M. os was well dilated, and the patient being etherized, the index finger was introduced, and most of the contents of the uterus was turned out, but a part was so adherent that it was necessary to use a curette. Arterial blood gushed out profusely. Very hot water was injected, but the bleeding continued, and it was necessary to tampon both the uterus and vagina. She came out from ether, and did well till the next morning, October 30th, about 5 A. M., when she had a severe chill. At 8.20 tampon was completely removed, and a vaginal injection given. At 9.30 temperature $103\frac{1}{2}^{\circ}$, pulse 110. At 5 P. M. the discharge had ceased, and temperature remained at $103\frac{1}{2}^{\circ}$. The uterus was washed out with a solution of 1 to 40 of carbolic acid, and 10 grains of quinine were given. Every three hours the uterus was washed out in the same way. At 9 A. M. the next day, October 31st, temperature was normal. At 3 P. M. temperature rose to 100° , and discharge ceased. Uterine douches were continued three days, once in three hours, and 10 grains of quinine were given twice a day until November 2d, when temperature was continuously normal.

During the night, about ten hours after the douches were stopped, she had a chill, and at 9 A. M., November 3d, temperature again rose to $103\frac{1}{2}^{\circ}$, when the injections were resumed and given regularly every three hours. 11 P. M. temperature was 99° ; after this she was allowed to sleep till morning. At six she had a chill, and at nine temperature was $103\frac{1}{2}^{\circ}$. The uterine douches were again resumed, and kept up, as before, once in three hours. Quinine was also given, but in smaller doses, and she was carefully fed. As before, in about fourteen hours temperature was $99\frac{1}{2}^{\circ}$; after this the uterus was syringed regularly until November 6th. The temperature remained normal after the first fourteen hours. Again she was allowed to sleep eight hours, but, as before, she awoke with a chill, and the temperature, at 9.20 A. M., November 7th, was $104\frac{1}{2}^{\circ}$. The uterine douches were again begun, and in twelve hours her temperature was normal. After this the douches were given by the watch once in three hours, and were continued day and night for seven consecutive days. She then slept all night and the next day; temperature continued normal, and from this time forward she made a rapid recovery without the least fever. Except during the first four or five days quinine was used only as a tonic; and during the eighteen days she was carefully fed, chiefly on milk and meat-juice. To give a short *résumé*: October 27th, 28th, and 29th, pulse weak and soft, but temperature continuously normal. October 30th, chill, fever, $103\frac{1}{2}^{\circ}$; uterine douches, given once in three hours, brought it down to normal in sixteen hours; douches kept up for twenty-four hours longer, and then stopped for ten hours; again chill, and temperature $103\frac{1}{2}^{\circ}$; douches were resumed, and in fourteen hours temperature again normal. Then, on account of patient being tired, she was allowed to sleep about eight hours; again chill, and temperature $103\frac{1}{2}^{\circ}$; douches resumed as before, and temperature normal in fourteen hours. Douches kept up for full three days, and again, after eight hours' sleep, chill, and temperature rose to $104\frac{1}{2}^{\circ}$; douches again, and in twelve hours temperature was

normal. Douches kept up for seven days, night and day, every three hours, and then patient allowed to sleep ten hours; after this there was no rise of temperature. I used then a gum-elastic catheter, No. 9, attached to Davidson's syringe by a rubber tubing, and, as the uterus was averted and sensitive, it was necessary for me to be present in person once in three hours, except at the interval indicated, for two full weeks.

This case taught me a great deal, and since then I have thus far been able to manage all cases that have come directly under my care, with much less trouble and excellent results.

About one year after this, on January 18, 1881, Mr. W. called, and said that his wife was very ill, and that he wished me to take charge of her case. Soon after, Dr. Griswold called to say that he had attended Mrs. W., that she had an abortion about four months, and was now in a critical condition, with undoubted puerperal fever. I saw her at 3 P. M.; she then had temperature 104.2° and pulse 120. At 4 P. M. her temperature was 105°. I then introduced a gum-elastic catheter into the uterus, which was enlarged, soft, and lying backward on the sacrum, attached a Davidson syringe, and injected about 2 qt. solution, 1 to 40, carbolic acid, bringing away considerable clotted blood and broken down *débris*. This I repeated every half-hour. In three hours temperature fell to 102°. At 11 P. M. I introduced the catheter and left it in the uterus, and put a trained nurse in charge, to repeat the douches once every half-hour during the night. No medicine was given by mouth. The next morning temperature was normal, and remained so, only going to 99° in the afternoon. A close watch was kept up for several days, and, as she had no further trouble, in ten days was allowed to go about, and made a good recovery.

Since then I have seen in consultation two other patients, in very much the same condition as the last, and both recovered under the same treatment. That is, after twelve hours of frequent douches, the catheter being left in the uterus, the temperature gradually fell to normal, and did not afterward go above 100°, and the patients recovered without further trouble.

I have come to the conclusion that it is best to consider a uterus after an abortion precisely as surgeons to-day regard a punctured wound, and just as likely to be poisoned and equally dangerous when neglected or badly treated.

1. That septic matter must be excluded with great care, and that antiseptics are of great service in preventing infection.

2. That perfect drainage is just as essential as in a severe contused and punctured wound; that not only versions, and especially flexions, may cause retention of the lochia, but that contraction and swelling of the os internum very frequently is an active cause in preventing a constant and free drainage.

3. That when septicæmia has begun within a reasonable time, say within ten or twelve hours after the first chill or high temperature, almost all cases may be cured by perfecting the drainage, and by washing out the cavity either of the vagina or of the uterus, as the case may be, by frequent douches of a solution of carbolic acid of a strength of from 1 to 40 to 1 to 20, the latter being rarely needed.

4. That general medication, except so far as it keeps up the strength of the patient, has little or no direct effect, and that the washing out with carbolic solution not only re-

moves or renders inert the organisms on the surface of the wound or cavity, but, in all probability, sufficient carbolic acid is absorbed locally into the surrounding tissues to weaken if not stop the active reproduction of the micro-organisms, or the generation of poison associated with them.

It is possible that antiseptics, such as pure carbolic acid or phenol, or mercuric bichloride, may be injected hypodermically to such an extent as to neutralize the bacteria or poison in the blood, without doing serious harm to the patient, or that large quantities of alcohol may antisepticize the blood; but I have never seen this clearly proved.

I am fully aware that many cases very soon reach a stage where neither local nor any other treatment can stay it, such as those where the poison has extended rapidly into the connective tissue, or has been carried a distance from the surface by the lymphatics or the veins, and started a new center of local poison; but I believe that most of these hopeless cases begin as simple cases, and, if treated in time, would never reach a dangerous stage—that is, that time gives the disease power, and may even develop stronger, and, therefore, more dangerous micro-organisms or poisons. I also recognize the fact that there are, probably, several different poisons, and also that the same poison in different tissues may give very different symptoms and results. But we must go back to the fact that the beginning, if not always, is almost always local, and that if we begin early, and continue frequently enough and long enough, to wash the parts with an antiseptic, we can in most cases remove the cause. I also believe that there are micro-organisms that even 1-to-20 solution acid. carbolic. will not destroy, or at least in a short time destroy all the spores and prevent their future reproduction under favorable conditions, but it is pretty well established that the presence of a 1-to-40 solution renders them innocuous, by either killing or weakening those that are produced. It is on this account that I use frequent and long-continued injections.

I do not advise intra-uterine injections in old cases. If the disease is confined to the vagina, apply antiseptics to the vagina, but do it often enough to keep up their influence for at least twelve consecutive hours. Usually, if the disease has lasted for several days, or if the symptoms are dangerous, it would be better not to delay washing out both the uterus and vagina, and do it vigorously and faithfully; and don't be satisfied with a uterine injection two or three times a day, or even once in three hours.

Now, as to whether it is best to keep up continuous irrigation, or to intermit for fifteen minutes or half an hour. I have had such satisfactory results with the latter method that I have never tried the former; but there is this much in favor of the intermitting plan: 1. It is more readily and with greater certainty carried out; 2. It gives the parts, if not the patient, a little rest; 3. If the spores are so difficult to kill, and the bacteria so easily killed or rendered inert, the spores may not hatch or attempt reproduction in a continuous stream, and, therefore, they are longer preserved, while in half-hour intermissions the acid may be absorbed and the spores be induced to develop sufficiently to be killed by the next or a later douche—if we wait even three hours the spores may develop, and new spores be reproduced be-

fore the next douche; 4. By douching at intervals, we can use stronger solutions, with less risk of poisoning with the antiseptic than when the continuous stream is employed. I have very little doubt but that repeated washing out with water would often effect a cure, but it must not be forgotten that water would mechanically displace and remove much of the decomposing matter, and also that pure water, if not destructive to, at least weakens the vitality of, many bacteria.

The late experiments of Koch and others give the mercuric bichloride the first place as an antiseptic, and it may replace carbolic acid in intra-uterine douches.

Now, what should guide us in the use of antiseptics after abortions?

The first symptom is usually a chill or chilly sensation, and stoppage of the lochia, and then a rapid rise of temperature. If, in such a case, on examination, an extensive laceration of the perinaeum, or the cervix, or wound of the vagina were found, I would wash out the vagina with a 1 to 20 solution acid. carbol. at first, and after this give a 1 to 50 douche regular every fifteen minutes or half-hour for three or four hours. If the temperature then fell gradually, I would continue the douche in the same way for twelve hours or more; but if, notwithstanding these vaginal douches, the temperature should continue to rise or go up rapidly after lessening for several hours, I would at once begin intra-uterine douches, giving one of 1 to 20, and after this 1 to 50 every half-hour until the temperature fell to normal.

In those cases that I have personally attended, the first douche generally brings away considerable *débris*, and the discharge is often bloody, but it gradually clears up with each douche, until finally it comes away clear; and, when it remains so for several injections, almost invariably the temperature is found normal.

It is important, especially in giving the intra-uterine douche, to be certain that your carbolic acid is pure, and I insist upon having Calvert's No. 1, for my experience is that this is about the best that can be had, and that, with the exception of Déclat's, and one or two German preparations, the carbolic acid sold in the shops will cause decided irritation even in solutions of 1 to 50, and many are to a degree more or less insoluble.

In private practice I have not had a case of septicæmia following labor. Four times I have seen patients with puerperal septicæmia in consultation. In three of these the disease had reached its last stage, two were actually dying, and the third in a hopeless condition. A few douches were given in the latter case, but did no permanent good.

The fourth case was that of a young woman who had been delivered three weeks and had no serious symptoms. She suffered from cystitis and subinvolution, and was in quite an anæmic and feeble state, being still confined to bed.

May 2, 1893.—She had a prolonged chill or chilly sensation in the morning; and when I saw her in the afternoon her pulse was 130 and temperature 104°, and she had the characteristic profuse perspiration and collapsed appearance of septicæmia.

On examination, the uterus was enlarged and soft, the fundus lying backward and sharply flexed at the cervix; the lochia had completely stopped. An intra-uterine douche of solution acid.

carbol., 1 to 80, was given, and a dirty, soft, brown clot and shreddy matter came away with the douche. The douches were kept up at intervals of about half an hour, and in two hours temperature had fallen to 102½°, and after eleven douches temperature was found normal. She remained in a feeble state, with a poor pulse, for several days, but her temperature did not again rise above 100°, and now she is going about in good health.

Soon after taking charge of my ward at Bellevue in October last, on account of the other wards of the fourth division being crowded, the following case was admitted and treated, under my instructions, by the house staff:

Rachel Bergowitz; thirty-eight; Poland; married; admitted to Ward 29 October 19, 1893.

Patient was a large, fleshy woman. She had had several children, and had been accustomed to get up and do her housework in three or four days after confinement. Had always been healthy. Examination of the chest and urine showed nothing abnormal.

Four days before admission she had been delivered of what she supposes was a full term child. The labor was a long one, and the child was dead when delivered. The placenta came away a few minutes after delivery. There was no unusual hæmorrhage.

The day before admission she had a chill in the afternoon, and after it felt very weak, and had pain in all her limbs and back. She was admitted about 9 P. M., nearly thirty hours after the first chill. At that time her temperature was 101°, pulse 100, full and soft. A dose of castor-oil and quinine, gr. xv, were given.

Her temperature was 101½° at 10 P. M., and rose steadily through the night, standing at 104° at 8 A. M.

October 20th.—A sponge bath and quinine, gr. xv, were given at 8, and the temperature fell to 103½° at 9 A. M. Up to this time it had been impossible to give intra-uterine douches, the house physician having charge of an ovariectomy case, and being unable to attend the patient.

At 9.30 A. M. an intra-uterine douche was given. A Mercier catheter, No. 12, American scale, was passed to the fundus, and about two quarts of water, carbolized 1 to 80 and heated to 110°, were thrown into the uterus. The douche caused no unpleasant symptoms, and the patient enjoyed it, saying that it relieved the pain which she felt in her abdomen.

At 10 A. M., immediately after the douche, her temperature was ½° higher.

Ordered whisky, ʒ ss., every hour, and quinine, gr. xv, every four hours.

At 10.15 A. M. she had a severe chill, and at 11 her temperature was 105¼°. At that time a douche, carbolized 1 to 40, was given, and brought away several dark, soft clots. At 12 the temperature was 102¼°, a fall of 3°. Douches were then given every hour, the temperature falling a little after each douche till 5 P. M., when the temperature was 100¼°. The patient then complained of the frequent disturbance, and the douches were omitted for about five hours. They were then given every four hours through the night, and the whisky ordered every two hours. At midnight the temperature was 98½°.

21st.—At 9 A. M. temperature 98½°. Whisky was ordered every three hours, and quinine reduced to gr. v q. 4 h. Vaginal douches were ordered every four hours, and intra-uterine douches if the temperature reached 100°. Two intra-uterine douches were given, both of them being followed by a fall of temperature to 98½°.

The patient had a slight diarrhœa during the day, and was given bismuth and opium in small doses. It stopped in the evening.

22d.—An intra-uterine douche was given at 1 A. M., after which the temperature reached 100°. Vaginal douches were continued, the whisky gradually stopped, and the patient was discharged November 5th in good health.

Since then nine cases of undoubted septicæmia after labor have been treated in the fourth medical division, in which, under Dr. H. F. Walker, Dr. W. T. Gillette, and Dr. J. J. Williams's instructions, the house physician used the intra-uterine douche. The histories have been carefully taken and written out by the house physician, Dr. Pardee, who personally carried out the treatment in most of these cases. Seven of the nine patients made good recoveries, and two died. One of these was admitted four days after the first chill, and was in too advanced a stage to prevent further poisoning by intra-uterine douches. In the other fatal case, it was afterward ascertained that a very large clot prevented the douches reaching the uterine cavity for more than twenty-four hours.

My experience with the dangers of intra-uterine injections is limited. In one case where there were symptoms of septicæmia after an operation on the cervix, I saw very great shock immediately follow an intra-uterine injection, but in that case a very small catheter was used; and, when the bed-pan was removed, not an ounce of the pint of carbolic-acid solution was in it, nor had it escaped on the bed, for the catheter undoubtedly entered the Fallopian tube, and the fluid was forced into the abdominal cavity. The patient recovered in eighteen months, after suffering during that time with an extensive pelvic abscess. Not long since, while passing from my special ward in Bellevue through the adjoining medical ward, the house physician, Dr. S. Alexander, asked me to see a patient with puerperal fever who was rapidly sinking. She had been brought in eight hours previously with a very high temperature. He had given one carbolized intra-uterine injection, which was followed by a slight convulsion and a fainting turn. This he attributed to the injection, and he did not think it safe to repeat it. Notwithstanding the use of quinine and other internal remedies, she now appeared to be in a hopeless condition; temperature 105°, pulse 130, with profuse perspiration, etc. I advised him to begin the injections at once and keep them up every half-hour, saying that I supposed the first injection might have such a result as he had described without doing serious harm. The woman rapidly improved under the frequent injections, and made a good recovery.

If a large tube, such as Chamberlain's, is used after the os internum is well contracted, it may hug the tube so closely as to cause the douche to distend the uterine cavity. When the fluid is injected under these or similar conditions, the fluid may be forced through the Fallopian tubes into the peritoneal cavity, or a clot may be forced into a vein or through a sinus and do harm; but if a gum-elastic catheter is used, with a two-and-a-half-inch mark to limit the length introduced into the uterus, and of small enough size to pass very readily, not only will the fluid escape, but it will frequently bring with it large shreds of *débris*, clots, etc. In many cases a somewhat flexible and adaptable tube is better than a glass or other

stiff tube. In those cases where the uterus is flexed or the os firmly contracted, these conditions should be rectified before the injections are given; and where there is imperfect drainage the catheter can be left in the uterus, and cut off, with a piece of soft rubber tubing attached to the end at the vulva, and the lochia caught by a carbolized napkin or dressing.

My object in reading this paper was: 1. To advocate preventive measures by the use of antiseptics in all abortions and lying-in cases for the same reasons as they are used in punctured and other severe wounds where the drainage is, if not imperfect, at least slow. 2. To recommend the frequent and long-continued use of antiseptic injections, when once begun, in cases of puerperal septicæmia, and to make it plain that three or four vaginal or intra-uterine injections given in twenty-four hours are not sufficient to do much good, and are likely to result in the disuse of the best, and in many cases the only means of preventing death from septicæmia. That, even when douches are given once every three hours, the disease may renew itself while the injections are being given or after they are stopped. To maintain that vaginal or intra-uterine douches of carbolic acid of a strength of from 1 to 50 to 1 to 20 will save almost all patients when begun early, and that it will often save in apparently hopeless cases.

I suppose that there are many here to-night who use the injections frequently and until the temperature is normal; but our very best text-books take up most of their space devoted to this subject in showing the danger of intra-uterine injections, and wind up with recommending their use three or four times in twenty-four hours.

THE CLIMATIC TREATMENT OF PULMONARY CONSUMPTION; REPRESENTING THE OPINIONS OF THE PROFESSION IN REFERENCE TO CLIMATOLOGY AND CONSUMPTION.

By J. HILGARD TYNDALE, M. D.,

NEW YORK.

CALIFORNIA.

Dr. F. W. Hatch, Sacramento, Cal., in his report on "Relations of the Climate of California to Consumption" (State Board of Health, 1877), very correctly divides the climatic regions of California into:

"1. The coast and the valleys bordering thereon.

"2. The interior valleys, as the Sacramento and San Joaquin.

"3. The Coast Range Mountains.

"4. The Sierra Nevada Mountains."

The following conclusions are reached: "First, that to the majority of invalids seeking a change of climate in consumption, the mountains—preferably the Coast Range—

offer advantages, during the summer and early fall months, superior to those of any portion of the State. Second, that a certain proportion may find the eastern slope of the Coast Range agreeable and beneficial even during the winter season."

Dr. H. S. Orme, Los Angeles, Cal.: "In considering the adaptability of southern California as a health-resort for consumptives, it is always to be kept in mind that it is not a so-called 'sedative' climate, nor, compared with some other States, such as Florida, can it be called a hot climate. Taking Los Angeles as a center, the mean temperature there during 1882, according to the official statistics of the United States Bureau, was 60°. The highest and lowest daily means were 100° and 32°, respectively, but no monthly mean was under 49° or over 71°. Taking equability of temperature, dryness, and elevation as factors in the arrest of consumption, I think they are all to be found in southern California; and though there are few very elevated places as yet established as resorts for invalids, there are localities of such elevation as to secure dryness and purity of atmosphere, for instance along the Sierra Madre Range, say from 800 to 1,800 feet of altitude. Further, it is to be stated that cases requiring a moist atmosphere, or sea-air, can find suitable accommodation at numerous points along the Pacific coast below Point Conception; for instance, Santa Barbara, Santa Monica, and San Pedro, in Los Angeles County, and San Diego, in San Diego County. On the whole, all the conditions of climate and points of elevation usually sought for by the consumptive can be found in one or other of the coast or inland health-resorts of southern California. So much for facts. As to my own opinion in regard to the class of patients I should send to a *sedative*, or, on the other hand, to a *sthenic* climate, and in the absence of any experience on the patients' part as a guidance, I should be guided by the peculiar condition and temperament of each patient, and should at first only recommend a more or less sedative or sthenic climate *for trial*, giving the patient such directions that, if he found the climate recommended to him for trial to have a prejudicial effect on his symptoms, he should, under medical advice, find such climatic conditions as should, in a reasonable time, benefit his condition. . . . It is well to observe that our extent of country is so considerable—some of our counties in southern California being as large as some of the Eastern States—that in the course of a day's journey any variety of climate may be experienced. In this county of Los Angeles, with its coastline of over 100 miles, and an average breadth east and west of about 60 miles, and intersected by ranges of mountains, a variety of climates is naturally to be experienced. If there is any objection to be made to the climate in general, it is only on account of the considerable difference between the temperatures of midday and midnight, and perhaps also the fogs, which at times are prevalent."

4. INLAND (MEDIUM ALTITUDE).

a. *Moderate dryness. Moderate equability.*

NORTHEASTERN GEORGIA.

Dr. H. V. M. Miller, Atlanta, Ga.: "My experience, and, I think, all observation, satisfies me that neither cold

nor hot climates, as such, produce or cure consumption. It is a disease of temperate climates, and is infrequent in both Arctic and tropical regions.

"Elevation, say from two to five thousand feet, is the first requisite of the ideal climate for all consumptives, except those in whom the disease is so far advanced as to render them incapable of the necessary increase of lung inflation. For these the mild, equable climate of Florida would probably be better if undue moisture can be avoided. Temperature is not important if it is not accompanied by sudden alternation or strong winds. Colorado has sufficient elevation, but, if I am correctly informed, is liable to the two last objections. Dryness and sunshine are important elements.

"*The southern slope of the Blue Ridge Mountains* is the most perfect climate within my knowledge. It has a general elevation of two or three thousand feet, with more elevated mountain range, rising to five thousand feet. On the southern side of these ranges are many locations sheltered from the north and west winds, with sufficient elevation, pure, dry atmosphere, pure water, genial sunshine, and freedom from malaria, alike suited to a winter or summer residence, except, as above stated, in cases of far-advanced consumption.

"With one small district of this large section I am very familiar; it is the county of Rabun, which you will find in the northeast corner of the map of Georgia. It has had a population of from 2,000 to 6,000 for the last sixty years; during that period, upon most careful inquiry I state, there has not been one single case of consumption. The United States census reports two cases, one a child and one grown person. I am fully satisfied, on personal examination, they were not so. No other district in the United States, I think, can show a like exemption. An isothermal line starting at Boston and crossing the continent would pass through this district, showing its exemption from the exhausting heats of summer and the rigors of winter. To this district I send all patients whom I think amenable to treatment."

b. *Dryness. Moderate equability.*

AIKEN, SOUTH CAROLINA.

Dr. W. H. Geddings: "Aiken is situated in what is known as the Sand Hill Region of South Carolina, a range of hills of moderate elevation, extending through that State and a portion of Georgia. It is about 120 miles from the coast, and far removed from large water-courses. It is some 600 feet above the level of the sea, and sufficiently elevated above the surrounding country to insure perfect drainage and complete exemption from malarial disease. Up to within a comparatively recent date, influenced by the tenets of Broussais regarding the inflammatory nature of phthisis, warmth was considered of paramount importance in the selection of a climate in the treatment of that disease, and consumptives were invariably sent to warm, soft, relaxing climates like that of Cuba and Madeira. It, however, soon became apparent to many that these warm, sedative climates, instead of curing the disease, tended only, in many cases, to hasten the fatal termination, and a violent reaction set in,

which culminated in our own land a few years since in the selection of Minnesota as a winter sanitarium for consumptives.

"As in consumption the heat-producing organ is involved, due allowance must be made in measuring the degree of warmth required for the deficiency of respiratory surface, and no preconceived ideas of the asthenic nature of this disease needing a stimulating climate should cause us to let an anemic patient freeze amid the snows of an Alpine climate. Without in the least deprecating the value of high mountain sanitarium, it must be acknowledged that there are many cases which are unsuited for such treatment, and in which a tonic, bracing climate, similar to that we are about to describe, is unmistakably indicated. The mean of the six colder months, November to April, which constitute the season of Aiken, is 51°77', or one degree and a half colder than the far-famed resorts of the Riviera. Of much greater importance, however, are annual and daily fluctuations as indicating the equability of temperature throughout a season. The average daily range of Aiken is 12°65', a degree of equability seldom met with north of Key West. The following table, compiled from reports on file at the Signal Office at Washington, gives a fair idea of the mean variation in twenty-four hours at Aiken as compared with that at other health-resorts.

HEALTH-RESORTS	September.		October.		November.		December.		January.		February.		March.	
	Deg.	Deg.	Deg.	Deg.	Deg.	Deg.	Deg.	Deg.	Deg.	Deg.	Deg.	Deg.	Deg.	Deg.
Key West	10.00	8.87	8.43	8.54	8.95	9.83	9.18							
San Diego	12.00	12.77	14.30	17.16	12.93	12.67	15.19							
Aiken	10.03	17.03	18.26	18.06	13.45	19.14	17.44							
Jacksonville	15.00	19.38	15.76	19.22	14.54	18.60	20.32							
San Antonio	14.36	25.33	23.15	21.33	22.22	22.05	16.16							
St. Paul	19.00	16.41	14.46	17.61	20.09	20.82	19.00							
Colorado Springs.	28.50	24.22	27.85	26.98	31.87	24.28	25.22							

"It will be seen that, aside from Key West, which is not regarded as a health-resort, Aiken is surpassed by but one station—namely, San Diego, Cal., and may therefore be classed among the most equable on this continent. The mean annual relative humidity at Aiken is 58 per cent., thus ranking it within 3 per cent. of the excessively dry climates as classified by Vivenot. In March, 1881, it was only 40 per cent., and in April, 1879, 50 per cent. These figures prove that Aiken is moderately equable and quite dry—in fact, the driest station east of the Rocky Mountains of which we have any reliable record. As would naturally be expected from the dryness of the atmosphere, the amount of vapor precipitated in the form of dew is relatively insignificant. *Who should go to Aiken?* The climate, being tonic and bracing in its character, is naturally indicated in chronic conditions of asthenic type: 1. *Bronchitis*, with more or less secretion. 2. Consumption in its various stages, except the last one, and all forms except acute tuberculosis and laryngeal phthisis. Persons with marked tendency to consumption (the pre-tubercular state), whether hereditary or acquired, in whom the disease is as yet undeveloped, are likely to be benefited by a residence in Aiken. Aiken is contraindicated in: 1. Laryngeal consumption, the air being too dry. 2. Laryngitis. 3. Bronchitis, when attended with

very tight cough and sparse secretion. Invalids should reach Aiken in time for the superb weather which prevails from the 1st of October to Christmas. The winter proper is very short, commencing usually about the end of December and extending through January and the greater part of February, during which period the air is clear and cold, with occasional frost, and even at this season of the year the cold is never so great or long-continued as to act injuriously upon any except such cases as I have previously mentioned as unfitted for this climate."

5. FAR ISLAND (HIGH ALTITUDE).

Dryness; no equability.

COLORADO.

(Eastern slope of Rocky Mountains.)

Dr. Charles Denison, Denver: "My experience, if I date back to my southern journey after pulmonary hæmorrhages, is only ten years, yet it embraces the most active period of an inquisitive mind. It was in the spring of 1873, in San Antonio, Texas, that I first conceived the plan of determining, if possible, the attributes of an *ideal climate* for consumptives. This, in view of the hopes inspired and grand results expected, became an ambition stimulating me to unusual exertion to acquire information.

"The two hundred and two consumptive patients, whose experience in Colorado and New Mexico was the basis of conclusions presented in my report to the International Medical Congress in 1876, have now increased to nearly six hundred, averaging over two examinations each by myself, and covering a combined residence in this section of probably somewhere near fifteen hundred to two thousand years. These patients are scattered from southern New Mexico to southern Wyoming; a few are in the east, in southwestern Texas and southern California, and a considerable number, of course, in their graves.

"I am willing to freely impart the information this experience can furnish in answer to the questions propounded. I wish, however, it were possible for such results to compass the obstacles surrounding this question of climatic relief more thoroughly than they do. By these obstacles I refer to the inherent peculiar difficulties existing at this stage of our knowledge of consumption.

"The *ideal climate* question finally turned out to be a very flexible theme, both as to the ideality of the climate and as to the phases and conditions of disease. It results that it is either impossible or wrong to give *positive* answers to the various questions that may be propounded, without due qualifications as to those phases and conditions of disease. Such qualified answers, perhaps as correct as I can now present, I have already given to nearly all the questions included in the circular in my report to the American Medical Association* in 1879 (see 'Transactions,' vol. xxx, pages 155 to 176), and more generally in my work entitled 'Rocky Mountain Health-Resorts.'[†]

* 'Experience of Consumptives in Colorado and some of the Aero-Hygienic of Elevations above the Sea,' with colored maps."

† 'Rocky Mountain Health-Resorts, an Analytical Study of High Altitudes in Relation to the Arrest of Chronic Pulmonary Disease.' Second edition, 1881.

"Before answering your queries, allow me to criticise the premises you state, in so far as they are to apply to my records. You state: 'We exclude all third-stage cases (with hectic, recent hæmorrhages, colliquative sweats, or diarrhœa), because we agree that they should remain at home.' And then you make the subdivisions to inquire about (1) superficial inflammatory processes; and (2) *cavities and infiltrations*, by which I infer you include some third-stage cases, i. e., 'cavities.' If this inclusion is a proper inference, then I agree with you, for I have seen many third-stage cases (the diagnosis being based upon any excavation) which have done excellently well out here, even though they had had night-sweats, hectic, or somewhat recent hæmorrhages. I have elsewhere observed* that 'the systemic influence of extensive disease in the first is often much greater than slight inroads of phthisis in the third stage'; and I would exclude as unfavorable for journeying from home: (1) first-stage cases with extensive involvement of lung disease and high fever, or marked evidence of tubercular condition; (2) second-stage cases of like character, and all of the second-stage class with less than half the lung tissue remaining free from active disease, for the condition of *softening* is of ominous import till the extent of that process can be established as limited; and (3) third-stage cases with more than one fourth of the lungs actively involved in disease, or all third-stage cases while in acute conditions or having colliquative sweats or diarrhœa, etc., inheritance, youth, and the female sex being unfavorable modifiers.

(To be concluded.)

AN EXTREMELY COMPLICATED CASE OF CICATRICAL CONTRACTIONS FROM BURNS.†

By ALFRED C. POST, M. D., LL. D.,

EMERITUS PROFESSOR OF CLINICAL SURGERY IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

Mrs. J. L., widow, aged thirty-two years, admitted into Presbyterian Hospital August 8, 1882.

On the 6th of June, 1881, she was severely burned in her face, hands, and forearms, by an explosion of gunpowder. Two months elapsed after the injury before the burned surfaces had healed. Indurated and prominent cicatricial bands were left upon the lower part of the face, extending from the chin to the ears, more extensive on the left than on the right side. The lobe of the left ear was completely enveloped in cicatricial tissue, a portion of its surface being exposed at the bottom of a deep pocket. The hands were greatly disfigured, and were scarcely of any use to the patient.

Right Hand.—The ring and little fingers were flexed at the metacarpo-phalangeal articulations, and at the articulations between the first and second phalanges. The little finger was thrown in advance of the ring finger, and any

attempt to straighten it was resisted by a firm cicatricial band, extending from the ulnar margin of the finger toward the pisiform bone. The point of the little finger was separated from the palm of the hand only to the extent of two centimetres. The ring finger was also fixed in a flexed position by a very firm cicatricial band on its ulnar margin, binding it to the ulnar margin of the hand, and resisting any effort to extend it beyond an angle of 120°. The index and middle fingers were nearly normal. The first phalanx of the thumb was bent forward at an obtuse angle upon the metacarpal bone, fixed by a cicatricial band passing from the radial margin to the wrist. The last phalanx was bent backward at an angle of 110°. The dorsal surface of the thumb was covered with cicatricial tissue, offering considerable resistance to efforts which were made to straighten the member at the articulation between the first and second phalanges. The integument of the forearm was covered around its whole circumference by moderately firm cicatricial tissue extending on the ulnar side to the vicinity of the elbow. The dorsal surfaces of all the fingers were webbed together, the spaces between the index and middle, and middle and ring fingers, as low down as the anterior edge of the commissures, and the space between the ring and little finger, nearly as low as the articulation between the first and second phalanges.

Left Hand.—Index and middle fingers are bent backward at the articulation between first and second phalanges, and firmly held in that position by strong bands of cicatricial tissue. The ring finger is flexed, almost at a right angle, at the articulation between the first and second phalanges, and fixed in that position by two nearly parallel cicatricial bands of considerable thickness. The little finger is flexed at an angle of 75° at the articulation between the first and second phalanges, and is firmly fixed by a dense mass of cicatricial tissue which occupies the whole space of the integument between the first and second phalanges, binding the whole of the middle phalanx to the palm of the hand. The first phalanx is bent far backward. The whole integument of the hand presents a cicatricial character. This condition extends upon the forearm, three or four centimetres above the wrist. The thumb presents a condition almost identical with that of the right hand. Masses of cicatricial tissue extend across the dorsal surfaces of the commissures of all the fingers, webbing them together more than half way to the articulations between the first and second phalanges.

FIRST OPERATION. August 10th. Right Hand.—Multiple division was made of the cicatricial bands, which fixed the ring and little fingers in a flexed position, and which contracted the palm of the hand. The fingers could then be extended and the tension of the palm relieved. The wounds were washed with carbolic acid, 1 to 20, and dressed with lint, saturated with carbolic oil, \mathcal{O} ij of carbolic acid to \mathfrak{z} ij of olive oil. A dorsal felt splint with digital prolongations was applied, fortified with strips of hoop-iron, one for each finger, the splints extending up nearly to the elbow. Each finger was fixed in an extended position to the corresponding portion of the splint with narrow strips of adhesive plaster. Wider strips of adhesive plaster secured

* Report to the American Medical Association, "Typical Cases of Phthisis, with Results" (in Colorado). "Transactions" for 1877.

† Read before the New York Surgical Society, May 22, 1883.

the splints to the forearm, and a gauze bandage was applied over the whole.

Left Hand.—An operation was performed similar to that on the right hand, except that the distal extremity of the proximal phalanx of the little finger was excised with bone forceps, after having been exposed by a longitudinal incision dividing the skin, the aponeurosis of the extensor tendon, and the periosteum. The dressings were the same as on the other hand.

15th.—The dressings were removed for the first time since the day of the operation. The wounds were washed with carbolic acid, 1 to 40, and dressed as before. They were beginning to granulate, and were free from inflammation.

18th.—Dressed as before; the wounds were in good condition.

26th.—The wounds have been dressed every other day, and passive motion applied to the fingers. The wounds are nearly healed.

September 11th.—The wounds are healed. The splints were left off from the right hand, and from the ring finger of the left hand, to allow passive motion of the fingers.

12th.—Reapplied splints.

16th.—Left off splints again for twenty-four hours.

17th.—As the fingers showed a strong tendency to re-contraction, the splints were again applied.

27th.—Splints removed at 6 A. M., and reapplied at 11.30 A. M.

SECOND OPERATION. October 4th.—This was performed to improve the position of the thumbs.

Right Thumb.—A longitudinal incision was made over the dorsal surface of the distal articulation of the thumb, exposing the bone. The distal end of the proximal phalanx was then excised with cutting forceps. Five transverse incisions were made across the longitudinal ones, but not deeper than the cicatricial tissue.

A similar operation was performed on the left thumb. The wounds were dressed in the same manner as after the first operation. The thumbs were brought into a slightly bent position, and secured in that position by dorsal splints of hoop-iron.

10th.—Renewed the dressings.

25th.—Since last date, the dressings have been renewed, and passive motion employed every other day. The wounds are nearly healed.

November 1st.—The distal phalanges of the thumbs are nearly in their normal position, but with some tendency to backward flexion. The metacarpal bones of the thumbs are adducted by strong cicatricial bands on their palmar and dorsal surfaces. The index, middle, and ring fingers of the right hand are nearly normal in position and mobility, while the little finger is maintained in a state of partial flexion and slight adduction by a dense cicatricial band, which extends along the palmar surface and ulnar edge nearly up to the wrist. The ring and little fingers of the left hand are still somewhat flexed at the articulations between the first and second phalanges, while there is some backward flexion at their metacarpo-phalangeal articulations.

THIRD OPERATION. November 1st. The cicatricial in-

tegments on the dorsal surfaces of both thumbs were freely divided by a series of oblique incisions intersecting each other at right angles so as to divide the aforesaid cicatricial integuments into a series of parallelograms about seven millimetres in diameter. On the left hand, the cicatricial tissues were also divided on their palmar surface by a series of parallel incisions extending over the radial margin of the thumb. The cicatricial webs uniting the several fingers of the left hand on their dorsal aspect were divided by one longitudinal incision in each interdigital space, and by a number of parallel transverse incisions on the lateral surface of each finger.

On the right hand, similar longitudinal incisions were made through the webs on the dorsal surfaces of the fingers; and nearly parallel with the longitudinal incision on the dorsal surface of the web connecting the dorsal surfaces of the index and middle fingers, a V-shaped incision was made, so as to liberate a triangular flap whose apex pointed upward about three centimetres above the commissure, the base of said flap, including the main longitudinal incision at the commissure. On the outer surface of the integument covering the first phalanx of the little finger and its metacarpal bone twelve transverse incisions were made through the contracted cicatricial tissue, which drew the finger in the direction of adduction and posterior flexion. The usual dressings were applied, but the application of splints was postponed until the next day.

2d.—The dressings were renewed, and splints applied to draw the several parts in the directions opposed to the deformity.

After the first few days, the dressings and splints were renewed every other day, and passive motion employed at each dressing.

FOURTH OPERATION. December 5th. Right Hand.—The principal remaining deformities to be overcome were undue approximation of the metacarpal bone of the thumb to that of the index finger, and abnormal flexion of the little finger. To overcome these deformities, free multiple incisions were made through the cicatricial bands occupying the commissure between the thumb and the index finger, and also through the dense band on the palmar surface and ulnar edge of the integument covering the little finger and its metacarpal bone. The thumb and index finger were then widely separated from each other and secured by splints of hoop-iron—one on the radial side of the thumb, and the other on the dorsal surface of the index finger. The little finger was brought into a state of exaggerated extension, and fixed in that position by a band of iron on the dorsal surface. All these splints extended above the middle of the forearm.

Left Hand.—The deformities to be overcome were, as far as concerned the commissure between the thumb and the index finger, the same as on the right side, and a similar operation was performed. The remaining deformity on this side was chiefly a flexed condition of the ring finger, involving the articulations between the first and second and second and third phalanges. This flexion was maintained by a very firm cicatricial band occupying the whole breadth of the palmar surface of the finger. I divided this band

by a number of parallel oblique incisions, downward and outward, intersected by other parallel incisions downward and inward. The finger was then brought into a state of exaggerated extension, and secured by an iron band on its dorsal surface.

December 10th.—The wounds have been dressed every other day. They are in a very good condition.

25th.—The wounds are nearly healed. The parts are maintained in a good position.

FIFTH OPERATION. *January 11, 1883.*—This was performed to relieve the backward traction of both thumbs at their distal articulations. It was similar to the operation performed on the 4th of October. It consisted in the excision of the distal extremities of the second phalanges, which were exposed by means of free longitudinal incisions on their dorsal surfaces. In addition to the longitudinal incision required for the excision of the extremities of the phalanges, multiple transverse incisions were made through the cicatricial tissue on each side. The usual dressings were applied to the wound, and the terminal phalanges of the thumbs were fixed in a flexed position by the application of bandages around them and the hands.

SIXTH OPERATION. *February 14th.*—The little finger of the right hand, and the ring and little fingers of the left hand, being flexed at angles of about 135° , multiple incisions were made across their plantar surfaces; the fingers were brought into a state of exaggerated extension, and fixed by means of splints applied to their dorsal surfaces.

SEVENTH OPERATION. *March 26th.*—The right little finger and the left ring and little fingers remaining still abnormally flexed, the operation of February 14th was repeated upon them, and they were again fixed by appropriate splints in a position of exaggerated extension. The left index and middle fingers being bent backward at the articulations between the first and second phalanges, by broad cicatricial bands on their dorsal surfaces, multiple oblique incisions were made, downward and inward, and downward and outward, dividing the bands into rhomboidal segments. These fingers were then bent forward, and secured in a flexed position by bent splints applied along their palmar surfaces.

EIGHTH OPERATION. *April 12th.*—The lobe of the left ear being enveloped in a mass of cicatricial tissue, I made a curved incision around its lower extremity and liberated it from its abnormal attachments, and then, by excising a small portion of the subcutaneous tissues, was able to reunite the integument over its margin, and to secure it by fine sutures. I also brought together and secured by sutures the edges of the wound upon the side of the neck from which the lobe had been liberated.

20th.—I removed the last of the sutures to-day. The margin of the lobe has healed, and the insulation of the lobe from the parts with which it had been incorporated is completely established.

NINTH OPERATION. *26th.*—This was performed for the purpose of improving the position and increasing the mobility of the right little finger, which was still somewhat flexed and considerably adducted, and whose replacement in its normal position was resisted by a very dense cicatricial band along the palmar surface and the ulnar margin of

the little finger, and of the hand. This band had been repeatedly divided, and the parts had been stretched, but, in consequence of the difficulty of applying force advantageously to overcome the adduction, not as much relaxation of the contracted tissue had been obtained as seemed desirable. On the present occasion I made numerous oblique incisions, dividing the cicatricial tissue into small rhomboidal segments, and brought the finger into a state of nearly perfect extension; I also overcame the adduction. But, after making as thorough a division of the cicatricial band as seemed to be advisable, it required some force in the way of traction to maintain the improved position of the finger. I washed the wounds with carbolic acid, 1 to 20, and enveloped the finger in sheet lint, moistened with carbolized oil.

To maintain the improved position of the finger, I resorted to the following method: I first applied an iron splint along the radial side of the index finger and of the forearm, the digital extremity of the splint being bent at an obtuse angle, so as to bring the finger into a state of forced abduction. The middle finger was then secured to the index by a broad strip of adhesive plaster, and in like manner the ring finger was secured to the index and middle fingers. The little finger was then brought into an extended position, and secured by a dorsal splint, and the adduction was overcome by drawing it firmly out and binding it to the other fingers by a broad strip of adhesive plaster. A gauze bandage was then firmly applied around the hand and forearm. The fixation of the index, middle, and ring fingers in a position of abduction seemed to be indispensable, as a means of overcoming the obstinate adduction of the little finger. It was an evil, but appeared to me to be an unavoidable one.

May 22d.—The treatment last described was continued, with some modifications, until the 17th inst., when the iron splints were discontinued and wooden splints were applied to the dorsal surfaces of the forearms and hands, secured by roller bandages. This change was made as a matter of convenience, the fingers having been brought nearly into their normal position, and but little active force being required to keep them in place.

The treatment of this obstinate case has been brought nearly to a close. The hands will require the support of bandages and splints for some time to come, and the persevering use of passive motion will be required to restore mobility to the fingers. The result of the treatment is not perfect, but, considering the difficulties of the case, it has been as satisfactory as might reasonably have been expected.

In reviewing this case, it will be observed that the deformities of the thumbs and fingers produced by the cicatricial contractions were of a very complicated character, owing to the fact that the hands had been severely burned both on their palmar and dorsal surfaces, and that the proximal and distal phalanges of the same member had been drawn in the opposite directions of flexion and extension.

In consequence of these complications, it was a very difficult matter to apply force in such a manner as to overcome deformity in one direction without increasing it in another.

In the course of the treatment, it became necessary, in several instances, to repeat the operation upon the same parts which had already been operated on, as the tissues which had been divided had reunited so as still to offer strong resistance to forces tending to overcome the deformity. And in each instance some benefit was derived from the repeated division of the cicatricial bands. If the deformity had been only in the direction of flexion, or only of extension, the problem would have been much simpler, and better results could have been obtained in a much shorter time.

Each operation was performed while the patient was under the anæsthetic influence of ether, and the repeated etherizations were well borne by the patient. No considerable amount of inflammation followed any of the operations. There was no sloughing at any time of even the most minute portion of the divided tissues, although in a number of instances cicatricial bands were divided into small segments. The divided parts began to assume a healing character within a very few days after each operation, and in most instances the healing process was complete within two or three weeks.

After each removal of the splints, before reapplying them, passive motion was freely employed. This often occasioned a considerable degree of pain, which, however, soon subsided after the reapplication of the splints.

Occasionally, when one or more of the fingers had been kept for many days forcibly stretched in a direction opposite to that of the original deformity, it seemed disposed to become rigidly fixed in the position in which it had been held. In such cases the splints were left off for a day or two, with directions to make free use of passive motion. But very soon there was a tendency to a return of the old deformity, and it became necessary to reapply the splints, and in some instances to redivide the cicatricial bands. These changes in the details of the treatment seemed to be necessary to prevent rigidity and to overcome deformity.

The treatment of a complicated case of cicatricial contractions, like the one which has been described, must necessarily be extended over a long time. The contracted parts must be very freely divided at many points through the whole thickness of the cicatricial tissue, and the parts must then be stretched as far as possible in a direction opposite to that of the deformity, and maintained in that position during the healing of the wounds and for a long time afterward. By perseverance in this course for a sufficiently long period, paying constant attention to the most minute details of the treatment, the case may be conducted to a successful issue. And, if the patient be careful to practice active and passive movements of the affected parts to a sufficient degree, the tendency to a recurrence of the deformity, and of the rigidity of the parts, will be finally overcome.

CELLULOSE CATHETERS.—A correspondent of the "British Medical Journal" relates the fact that a patient of his broke one of these catheters after having used it only a few times. He considers them "safe only in the hands of skilled persons."

SEIDLITZ POWDERS are quite efficient if taken after the disagreeable oozing has ceased.

Correspondence.

LETTER FROM BUFFALO.

The Late Meeting of the Medical Society of the County of Erie. — A State Examining Board. — The Question of the Cadets. — Quackery. — The Prosperity of Doctors. — The Sanitary Condition of the General Hospital. — County Post-mortem Examiners. — Small-pox.

BUFFALO, JUNE 15, 1883.

THE advent of summer has lessened a little of the interest in the various medical societies of the city; and yet it was contrived to have a very exciting time at the Erie County Medical Society, which met yesterday. There was an unusual attendance at the morning session, some sixty of the members being present. After an *entrée* of fresh eels in a shivery kind of fish, which was washed down with spicy remarks and a few bottles of sour wine, the banquet was continued as follows: Some one proposed that the society should pass a resolution favoring the establishment of a mixed State Board of Examiners. This was a signal for a skirmish. The elders of the profession were against the word "mixed," and the younger in favor. The vote was called for; the young men were thirty-two, the elder twenty-eight. One of these last then questioned the right of some of the opponents to vote, they not having signed the constitution or paid their fees. Then the secretary poured cold water upon him, by saying no new member in the last fifteen years had signed the constitution. Finally the mixed State board carried the day. The resolutions were as follows:

Resolved, That it is the belief of this society that the present method of training and licensing physicians does not command the entire confidence of the profession or of the people.

Second, That the system of licensing physicians by a State Board of Examiners representing the legally authorized medical profession, as seen in operation during the past six years in the State of Illinois, is a decided improvement upon that now pursued in this State.

Third, That this society hereby indorses the principle seen in the formation of mixed boards of examiners—that is, boards giving in one body *pro rata* representation to all the different schools of legally authorized physicians, and believes that it is through the agency of such boards that the standard of medical education may be most efficiently advanced, the profession most advantageously controlled, and its ranks recruited by the admission only of persons worthy of its high responsibilities.

Fourth, That this society hereby pledges its best ability and endeavor to the cause of securing to the people of this State the services of such a board of examiners.

Fifth, That to this end a committee of seven members be appointed at this meeting, to be known as the Committee on Legislation, and that this committee have full charge of this matter, with power to call special meetings of this society, to confer in the name of this society with other societies and with individuals upon matters germane to this subject, to draw orders upon the treasury of this society in sums not to exceed \$100 for all legitimate expenses incurred in the prosecution of this work, and with such other power as, rightly used, would in its judgment aid to bring about this greatly desired end.

Thus ended "the feast of reason and flow of soul." At the afternoon session there was a *surprise* arranged, some seven being present. A little, old German doctor, who had tried vainly in the morning to present a paper on the eels (if, alas! his written on over forty pages of loose, old, soggy paper with the perseverance of a mosquito until he was rewarded. The little man, otherwise very harmless, gentlemanly, and modest, seemed transformed into a perfect fiend in the afternoon, and brandished his enormous roll of manuscript like a troll until we sank into our

chairs despairing. He said it would occupy but twenty minutes. We listened a mortal hour—at the end of which time a motion for adjournment was almost immediately made, and no one waited until it was carried. Most of us prefer now neither to hear nor read anything about the codes. There has been a pandemonium about our ears. It is only when we are held button-holed in a corner by a code-demon that we care to listen—squirring; or when a writer lures us into some Kantian article by beginning, "Here is the whole thing in a nut-shell." There is but one word to be changed in the new code to make it acceptable to all: to put the word "interfere" in the place of "consult"—"a physician may interfere with" any qualified practitioner, instead of he "may consult" with one.

The Committee of Censors of the Erie County Society has made considerable progress in the eradication of quacks. Several have been driven out of the city, to take root in some better-manured soil. One Beyermann leeches, bled, and blistered a young man with consumption into the grave in three weeks, which brought him before the police justice, where he was fined heavily and banished from the city. Clairvoyants who have advertised their coming to the city, on finding out how vigilant the Censors are, have canceled their engagements. There are still, however, a number of quacks in the city, whom, for lack of witnesses, it has been difficult to convict. Since the Governor did not sign the bill which would have legalized our Hamburg Canal College here, and probably have soon led to the distribution gratis of medical diplomas at second-hand clothing stores, the Censors can proceed with their exterminations. An injunction is about to be issued against said Hamburg Canal College, where lectures, by the way, are still going on by the *faculty*, with which name one Brayton and a Canadian named Bonnar are dignified. The position, professionally, of the "faculty" can better be imagined than described when it is stated that it is ostracized by even the homeopathic society.

The growth of Buffalo having been enormous lately, she is constantly adding to her many hundred doctors from all sources—chiefly from New York, Philadelphia, and Canada. Canada being so near, it is no trick at all to come from the farms just across the river to become a doctor in Buffalo, and such as come can easily change their brass to gold—good alchemists are they not?

To tell the truth, however, Buffalo is not a paradise for doctors. It has a reputation for being one of the healthiest places in the Union. Our heavy winds blow away many a pestilence. The young doctor is put to a great deal of strategy and patience in order to succeed. Contrary to what one reads of in other places, and in the "Diary of a Young Physician," the older physicians here are very kind to beginners. I am sure I know of none who would not be glad to give to incipient successors whatever it was utterly impossible for him to keep himself; and this is more than they are reputed to do elsewhere. Those not blessed by these occasional morsels are obliged to make the best of their various talents to gain a livelihood. One can nurse, one write for the daily press, one do surveying or civil engineering, one write short-hand, some get an office after much beer with politicians, some follow sick-looking individuals in the streets to make patients of them, some get their names before the public by being *au fait* with reporters, and some—why, some marry—but this only at the last struggle. It is really surprising how from comparative obscurity one can rise to somewhat of social position and wealth by marriage.

The General Hospital has suffered some losses of late. Sanitarily it can not be said to be in the best condition. Some time last spring a homeopathic doctor sent for one of our regular physicians (from whom I learn these particulars) to see several of his nine children who had diphtheria in its most malignant

form. Four of these died within a day or two, when the whole family was sent to the hospital and isolated in a wooden pavilion. Here I believe three more of the children died. Then the nurse who had charge of these cases contracted the disease and died. Following this, the chief of the training school for nurses, which is connected with the hospital, caught diphtheria, and lay for a week at death's door, but at last rallied. Several nurses, had at the same time sore throat, and one scarlet fever. Finally, Dr. John P. Gray, the senior assistant interne, fell a prey to the destroyer, dying about two weeks ago very suddenly from oedema glottidis, consequent upon the diphtheritic throat affection. The old portion of the General Hospital, containing the medical and surgical wards, was built before the war, and seem, apparently still to contain the contagion emanating from wounded soldiers in war-time. It has been reported, I think, by one of the internes, that sixteen consecutive cases of compound fracture have terminated fatally in these wards, and this in spite of frequent disinfection of the building. It is but fair to say, I presume, that some of these patients died from shock and hemorrhage. It is a marvel to many that Buffalo, although containing fully one hundred and eighty thousand inhabitants, has no city hospital.

Among the evils of making post-mortem examinations is the danger of blood poisoning. I suppose such cases are quite common. The death of a young Chicago doctor from this cause was recently reported. The junior assistant of the Buffalo General Hospital was poisoned while making an autopsy a few weeks ago, the disease taking on the worst form of pyæmia, and it is said that the young man, Dr. Schofield by name, can not recover. It seems strange that some method is not devised to avoid such risks. The gentleman who lectures on pathology at the medical college tells me the only safeguard is cold water, and plenty of it, while working in such dangerous material.

Speaking of autopsies reminds me that this county appoints two post-mortem examiners yearly. These offices, being purely political, fall into the hands of those young men who can afford to make associates of the worst class of politicians. Some amusement has been excited by one of those doing duty at present as such, because of his post-mortem diagnoses. For instance, he made an extremely careful scrutiny of all the organs in a man found dead, returning as a cause of death "cessation of vital function." Another was reported as "pyæmia"—in a person who died four hours after being run over by the cars. One of the yellow clots found frequently in the heart after death was mistaken by the doctor for fatty degeneration, and the certificate of death made out accordingly. This is on a par with the student who, upon being asked what muscle lay opposite the *corrugator supercilii*, responded the *alligator supercilii*, who invariably spoke of the *Ethiopian* tubes of the uterus, and who described the *tania solium* as a part of the brain in the neighborhood of the ventricles. Is not a State Board of Examiners needed?

Through the spring quite a number of cases of small-pox have been met with in the city, some thirty or more, and their origin has been traced to one of our rag warehouses. Health Physician Phelps has been assiduous in his duties, tracing these cases to their cause, sending the patients immediately to the pest-house, burning their contaminated effects, and vaccinating everybody in their neighborhood, and deserves a compliment for being one of our few good public medical officers.

FEMALE MEDICAL STUDENTS IN PARIS.—According to "Lyon médical," the number of ladies studying medicine in Paris in 1880-'81 was fifty-two, and in 1881-'82 thirty-nine, the latter number including ten French women, eleven English, five American, nine Russian, and one Hungarian, Polish, Roumanian, and Indian, each.

Book Notices.

A Treatise on Insanity in its Medical Relations. By WILLIAM A. HAMMOND, M. D., Surgeon-General United States Army (Retired List), etc. New York: D. Appleton & Co., 1883. Pp. xiii-9 to 767, inclusive.

First Notice.

THAT Dr. Hammond, with no asylum service to draw upon for the clinical basis of a work on insanity, should have been able to produce so masterly a book on that subject is a striking reminder, if any were needed, of the versatility of his talents, of his knowledge of medicine as a whole, and of his possessing a self-reliance bordering on genius. It has not escaped him that the reader's wonder would be raised by so daring an attempt, for he says in his preface: "Finally, the objection may be made that, not being the superintendent of a lunatic asylum, I have no business to set up as an authority on insanity, much less to write a book on the subject." To this objection he opposes, and quite justly, we think, his long career as a lecturer on diseases of the mind and nervous system, and adds: "Though I can not claim to have seen so many cases of insanity as the average superintendent of an asylum with its thousand inmates, I do claim that a single case thoroughly studied is worth more as a lesson than a hundred that are simply looked at, and often from afar off. The medical student who dissects one human body is likely to learn more of anatomy than the janitor who sees hundreds of corpses brought to the dissecting-room." He would have been abundantly justified had he chosen to supplement these remarks by a hint that for several years past he has been known to the profession as a man well versed in psychiatry, and that on that account many difficult and unusual cases of mental alienation must have been brought under his observation as a consultant, so that in reality his opportunities for becoming practically acquainted with the more out-of-the-way aspects of insanity have been ample, while whatever defects there may be in his experience fall mainly under the two heads of a deficiency in the number of ordinary cases observed and of a lack of systematic records of the slow progress of the cases he has seen. The defect first mentioned is scarcely worth mentioning; the second he has been able to make good in great measure by a study of the case-books kept by Dr. R. L. Parsons while he was the superintendent of the City Lunatic Asylum. We can not admit, then, that Dr. Hammond has been presumptuous in the matter of a lack of qualification, but, on the contrary, must give him credit for having acquired the qualification in the face of difficulties that few would have had the courage and the persistence to meet and overcome.

It is only within a comparatively short time that American physicians as a body have displayed any considerable interest in the subject of insanity. For many years Dr. Ray's work was almost the only systematic book of American origin that dealt with that branch of medicine. The times were ripe, therefore, for the appearance of such a treatise as Dr. Hammond has given us, as shown by the almost simultaneous issue of a work by Dr. Stearns, of Hartford, and the promise of a book in the same department by Dr. McLane Hamilton.

Confining ourselves at present to Dr. Hammond's treatise, in this preliminary notice we can only indicate its general scope, reserving a consideration of its individual parts for a subsequent article. The book is divided into four sections, three of which, embracing upward of two hundred and fifty pages, lead up to the subject proper. Section I deals with the general principles of the physiology and pathology of the human mind, including a consid-

eration of the nature and seat of the mind; its perceptual, intellectual, emotional, and volitional actions; the influence of individual mental and physical peculiarities upon its operation; the conditions known as eccentricity, idiosyncrasy, and genius; and the ætiological significance of habit, temperament, constitution, hereditary tendency, age, sex, and race, in relation to insanity. Section II treats of the nature and seat of instinct. Section III is devoted to sleep and dreams. Section IV embraces definitions and descriptions of insanity in general, and of its various forms (classed as perceptual, intellectual, emotional, volitional, compound, and constitutional), with closing chapters on the causes, prognosis, diagnosis, pathology, and treatment of insanity.

General Physiology of Muscles and Nerves. By Dr. I. ROSENTHAL, Professor of Physiology in the University of Erlangen. With seventy-five woodcuts. New York: D. Appleton & Co., 1881. Pp. xv-324. [International Scientific Series.]

THIS little book, though appearing in a popular scientific series, and therefore necessarily limited in its scope, is by no means an elementary treatise. Beginning with an explanation of the simple phenomena of muscular contraction, the author condenses into six chapters our present knowledge of the physiology of that subject. The last nine chapters are devoted to nerve irritability, and are not very easy reading. As the writer descends more deeply into the discussion, we can conceive that the non-scientific reader might be somewhat puzzled. The volume has appended several graphical representations of nerve and muscle contraction. One can not look over the book without feeling how difficult it is for a German to write a scientific primer. He must be exhaustive, or nothing. Perhaps Professor Rosenthal has come as near to being popular as his subject and erudition will allow.

BOOKS AND PAMPHLETS RECEIVED.

Atlas der Gelenkrankheiten nebst diagnostischen Bemerkungen und einem Abriss der Anatomie der Gelenke. Von Dr. August Schreiber. Mit xlii theilweise in Farbendruck ausgeführten lithographischen Tafeln und 56 Holzschnitten. Tübingen: H. Laupp, 1888. 4to, pp. viii-100. [Price, 12 M.]

Hand-book of Electro-Therapeutics. By Dr. Wilhelm Erb, Professor in the University of Leipzig. Translated by L. Putzel, M. D., Neurologist to Randall's Island Hospital, etc. With thirty-nine woodcuts. New York: William Wood & Co., 1888. Pp. xi-366. [Wood's Library of Standard Medical Authors.]

Bacteria and the Germ Theory of Disease. Eight Lectures delivered at the Chicago Medical College. By Dr. H. Gradle, Professor of Physiology, Chicago Medical College, etc. Chicago: W. T. Keener, 1888. Pp. 219.

On the Relations of Micro-Organisms to Disease. The Cartwright Lectures, delivered before the Alumni Association of the College of Physicians and Surgeons, New York, February 19, 21, 24, and 27, 1888. By William T. Belfield, M. D., Lecturer on Pathology and on Genito-urinary Diseases (Post-graduate course), Rush Medical College, Chicago. Reprinted from the "Medical Record," February and March, 1888. Chicago: W. T. Keener, 1888. Pp. 131.

State Charities Aid Association. Hand-book for Hospitals. New York: G. P. Putnam's Sons, 1888. Pp. 263. [Price, \$1.]

Gout in its Protean Aspects. By J. Milner Fothergill, M. D., Member of the Royal College of Physicians of London, etc. Detroit: George S. Davis, 1888. Pp. viii-303.

Annual Catalogue of the Albany College of Pharmacy, Department of Pharmacy of Union University, for 1882-'83; and Announcement for the session of 1883-'84.

FRANK F. FOSTER, M. D.

NEW YORK, SATURDAY, JUNE 23, 1883.

THE ALLEGED DANGERS OF SMOKING CIGARETTES.

THE extent to which the cigarette has supplanted the cigar of late years makes the question of the comparative noxiousness of the two a matter of considerable importance to smokers. All sorts of notions in regard to the subject are rife in the community—mostly to the disadvantage of the cigarette. It is said that the flourishing cigar trade of former times has been brought low by the intrusion of the cigarette, on which, the dealers assert, but a trifling profit is made in comparison with what they have been accustomed to realize from the sale of cigars. It is not unlikely, therefore, that some of the perils commonly supposed to attach to the use of cigarettes are ingenious figments inspired by the trade. At least, they are ridiculous enough to have had such an origin.

One of these supposed perils is that arising from the action of deleterious compounds formed by the combustion of the paper wrapper. It is even asserted that the paper used in making many brands of cigarettes contains matter that is poisonous without the intervention of the burning process, and arsenic is usually mentioned in this connection. Were this substance, or any of its compounds, really present, in anything beyond an infinitesimal amount, it is manifest that it would be apt to find its way into the system not only by being dissolved in the saliva, but also by being volatilized and taken into the mouth with the smoke. Such being the case, serious and unmistakable instances of arsenical poisoning would long before this have been traced to cigarettes if there were any truth in the story. Without pretending to have submitted cigarettes to chemical tests for arsenic, we think it may fairly be assumed that the lack of such occurrences as we allude to constitutes respectable negative evidence regarding the presence of that substance. Moreover, the matter has been so much talked about as to make it almost incredible that our zealous sanitarians would not have interfered to stop the sale of such cigarettes before now, had they been able to detect the arsenical contamination.

So far as concerns noxious products of combustion, less is said, and probably there is little to be said. Any effect produced upon the smoker by the empyreumatic substances in question can scarcely be materially different from what would be exerted by compounds of the same order arising from the combustion of almost any organic material destitute of specific properties. Moreover, such effect must be nothing more than local, manifested in the mucous surfaces with which the smoke comes in contact, but in no wise spreading to the general system.

Another allegation is, that cigarettes are sophisticated with some preparation of opium, in order to heighten their action on

the nervous system. If we compare the market value of tobacco with that of opium, we shall not feel inclined to dwell long upon this suggestion, for everybody knows that it does not suit the purposes of the falsifier to adulterate a cheap commodity with one that is expensive.

Coming now to more reasonable objections to the cigarette, it is urged that they encourage more frequent smoking than is common with those who use cigars, and that there is also a great temptation for the cigarette-smoker to inhale the smoke. Concerning the first of these suggestions, it is undoubtedly true, but it should be remembered that it takes a number of cigarettes to equal a cigar in narcotic effect. Cigarettes differ among themselves, of course, and so do cigars, but, taking all sorts into account, the statement will still stand, we think. The cigarette has indeed this advantage, that, being cheap, it is more likely than the cigar to be consumed only in part; and it is the practice of smoking either the one or the other to the very end that seems to be particularly mischievous. During the consumption of the first part the smoke has to make its way through the material intervening between the lighted end and the mouth, whereby a very large proportion of the offensive matter is filtered out from it that would otherwise be carried into the mouth and deposited there. Possibly also some of the nicotine is thus entangled. Now, the shorter the cigar or the cigarette gets to be in the process of smoking, the less of this filtering action takes place.

The practice of inhaling the smoke, *i. e.*, of taking it into the lungs, is undoubtedly more apt to be fallen into by cigarette-smokers than by those who use cigars or a pipe. It can scarcely be doubted that the habit is much more pernicious than ordinary smoking, for thus the smoke comes in contact with a vastly amplified absorbing surface, and, moreover, it is exceedingly probable that some of the matter with which it is laden is deposited in the air passages. We can speak but little more favorably of the practice of blowing the smoke out through the nose, for that, too, exposes an extensive absorbing surface to the smoke.

It appears to us, then, that there is no just ground for looking upon cigarettes, used with proper precautions, as in any way more capable of doing harm than either cigars or pipes.

THE SUMMER SOCIETY MEETINGS.

THE strictly local societies, which, although small in numbers and representing limited sections of the profession, yet do by far the greater part of the scientific society work accomplished in this country, and, indeed, nearly all of it that is of a clinical nature, hold all their meetings in the nine cooler months of the year. During that period the larger colleges are giving their regular lecture courses, and at the hospitals the operative work is brisk. Perhaps it is to these circumstances, quite as much as to the inspiring influence of cool weather, that the activity of the local societies during the term alluded to is to be attributed; for men never feel so much inclined to continuous work as when they have a good deal of it on hand.

No sooner does the season draw to a close, however, than the national and State organizations take up their parable—even somewhat in advance of the cessation of active work by the city societies. Among the larger States, Pennsylvania leads off in May, and Ohio and Massachusetts follow in June. Our own State Medical Society, indeed, holds its meeting in mid-winter, but in this practice it is almost alone. A few years ago a meeting was held in June, and attempts have been made at various times to have a summer meeting made the regular order, but thus far they have not proved successful. There have been two great reasons for these efforts to effect the change—the fact that physicians find it less convenient to leave their business to take care of itself for two or three days at a time in winter than in summer, and the virtual occupation of Albany by the Legislature during the former season. These considerations certainly seem to be of some importance, but, on the other hand, however detrimental it may be to a man's material interests for the time being to break away from them during the busy season, it may be that in the end just that little diversion is what saves him from the necessity of beginning his summer vacation perforce at an earlier date than the requirements of his business warrant. At all events, the February meetings of the State society are usually well attended, and it is hardly likely that a change will be made.

The county societies of this State, most of them, are so far from following the example of the parent organization that the great majority of them hold their annual meeting some time between the middle of May and the middle of July. It is at this season, too, that the national bodies start up into activity. At the approach of summer the American Medical Association, meeting sometimes in May and at other times in June, the American Surgical Association, the American Laryngological Association, and the American Neurological Association convene, while the American Ophthalmological Society and the American Otological Society follow in July, the American Dermatological Association holds its meeting in August, and the American Gynecological Society brings up the rear in September.

A summer meeting seems almost a necessity for these national societies, on account of the great distances that many of their members have to travel in order to attend, occupying time that could scarcely be spared in winter. In regard to those that meet in July and August, however, it must be that they suffer somewhat by the absence of certain of their members from the country; but there seems to be no other objection, inasmuch as they avoid the large cities, and meet at some place of summer resort.

A "MIXED" STATE EXAMINING BOARD.

In a recent issue we favored the establishment of a State examining board for conferring the license to practice, the board to be independent of the teaching bodies. We then said that on a subsequent occasion we should say something as to the best methods of attaining the end in view. It is not our present purpose to give our impressions fully upon the matter, but

there is one particular aspect of it that has lately been made prominent by the action of the Medical Society of the County of Erie in favoring a "mixed" board, as will be seen by the resolutions given in the letter from our Buffalo correspondent.

The broad question of the establishment of State examining boards has had the serious attention of many of the best men in the profession for some time past, and our information in regard to the recent meeting of the American Medical Association is, that, although the matter received little or no open discussion, it was the subject of a good deal of informal talk among the members, many of whom looked upon it as the coming question with the profession. The fear was freely expressed, however, that the proposed measure would meet with the determined opposition of the less reputable of the colleges, as they could not fail to see in its operation the gradual but sure extinction of their prosperity. We do not think that such opposition would prove formidable with legislative bodies, however boldly it might lift its front in professional circles. Legislators are ready enough to take questionable institutions under their wing whenever they think they smell an attempt at persecution, but a proposition looking only to the public welfare, and manifestly divested of sectarianism, they are not likely to smother merely on account of the ulterior disadvantage that it may be expected to work to corporations which, so long as a semblance of persecution can be appealed to, they are fond of coddling.

The action taken at Buffalo seems well calculated to deprive the scheme of anything that can be tortured into a manifestation of sectarianism. We are not prepared to admit, however, that it was necessary to go so far as to advocate a *pro rata* representation of the various sects recognized by the law. It will doubtless be found necessary to have each of the three legalized sects represented by an examiner in therapeutics, but, as to the examiners in the other branches, nothing will be gained for the cause of professional elevation if sentimental considerations are allowed such play as to interfere with the design of making the board perfectly competent and above all temptation to trade votes. Sectarianism in medicine is limited to the narrow field of therapeutics. If we can secure an arrangement by which no man can be admitted to practice medicine in the State unless he proves himself to possess a reasonable knowledge of all the other branches, we may safely leave therapeutics to take care of itself; but, once open the door to incompetence in three or four of the branches into which, for purposes of examination, medicine has to be divided, and reform is defeated. At present, therefore, we must look upon the proposition to create a "mixed" board with only partial approval.

THE NEW HEALTH COMMISSIONER AND THE SANITARY INSPECTORS.

SOME apprehension has been expressed that the new health commissioner was about to display his zeal for the public welfare by insisting that those medical gentlemen who hold the position of sanitary inspector should devote their whole time to the duties of the office, and, consequently, be debarred from

engaging in the practice of medicine. By pursuing this course, General Shaler might perhaps do something toward placating that particular element in the opposition to his confirmation by the Board of Aldermen which, when one of the board had spoken eulogistically of the general, remarking that he had witnessed his demeanor in battle, called forth the taunting query whether it was on a certain twelfth of July, when the walls of the houses were bespattered with the blood of innocent men and women, the aforesaid "innocents" having mustered for the avowed purpose of committing a breach of the peace.

It is not by reason of any increased efficiency on the part of the inspectors in the performance of their duties, however, that General Shaler could at all ingratiate himself with the demagogues by the policy to which we have alluded, but by compelling those of the inspectors who have anything better to look to in the future than the paltry pay allowed them to resign, thus opening fresh fields for the distribution of spoils among a herd of incompetents.

If the new president of the Board of Health thinks it better to play the part of a "boss" than to consult the real interests of the sanitary service of the city, he will insist that the sanitary inspectors shall be inspectors and nothing else. If, on the other hand, he seeks only to promote the efficiency of his department—and this for the present we prefer to believe—he will be perfectly justified in taking all possible means to insure the thorough devotion of the inspectors to their duties, but not in resorting to measures that can only result in the lapse of the offices into the hands of a set of incapables.

MINOR PARAGRAPHS.

THE LONG ISLAND COLLEGE HOSPITAL.

THE third annual dinner of the Alumni Association of the Long Island College Hospital was given at the Hotel Brighton, Coney Island, on Monday, the 18th inst. The large dining-room was well filled, the company including, it was estimated, about one eighth of the alumni. The president, Dr. James Watt, occupied the chair. Dr. W. H. Dudley spoke to the toast of The Long Island College Hospital; Mr. Mead to that of The Regents; Dr. S. G. Armor to that of The Faculty; the Rev. Dr. McClellan to that of The Clergy; Mr. Peters, of the "Eastern District Times," and Mr. Ford, of the "Brooklyn Union," to that of The Press of Brooklyn; Dr. William C. Wile, of Sandy Hook, Conn., editor of the "New England Medical Monthly," Dr. Landon Carter Gray, of the "American Journal of Neurology and Psychiatry," and the editor of this journal, to that of The Medical Press; Dr. J. G. Johnson to that of The Medical Profession of Brooklyn; and Dr. (then Mr.) Pearce to that of The Class of 1883. Among the other speakers called upon were Dr. J. S. Wight, of the faculty; the president of the class of 1883; Dr. Robert Newman, the newly elected president of the association; Dr. Johnson, a colored graduate of the college; and Dr. A. J. C. Skene, of the faculty.

From the remarks of the various speakers it was gathered that the institution had been in existence twenty-four years; that it was one of the first medical colleges in this country, if not the very first, to conduct its teaching under the same roof with a hospital service; and that, of those who came up to the degree of doctor in medicine this year, twenty-five per cent.

were rejected. The colored graduate spoke feelingly, but without bitterness, of his vain efforts to get admission to other colleges, and gratefully of the kindness he had met with at the hands of his alma mater. The clear inference from this pleasant occasion was, that the college was following its career creditably and most successfully.

On Tuesday, the 19th, the annual commencement was held at the Brooklyn Academy of Music. The Rev. Dr. Hall, of the Church of the Holy Trinity, addressed the graduating class, and the degree of doctor in medicine was conferred on the following-named gentlemen:

William Henry Aten,	Samuel Richard Kirkland,
Frank Sheldon Atwell,	Charles Francis Kuhn,
John Wilton Barlow,	John Baine Laidiey,
John Henry Bowen,	John Lincoln Macumber,
George Sanford Bowen,	Frank Orlando Manning,
Augustus Harper Buckmaster,	E. L'Honnemedieu McGinnis,
Frank E. Carpenter,	Henri Goulden McGrew,
Lorenzo Bliss Chapman,	Joseph Merzbach,
Andros Palmer Chesley,	James Allen Nichols,
William Albert Cottle,	Haydn Nichols,
Edward Payson Crowell,	Eugene Frederick Pearce,
Milton Burr Davis,	Charles Page Peterman,
Daniel P. Deming,	Jeremiah Daniel Phelan,
John Nicoll Dimon,	Samuel Howard Phillips,
Garland Ben Foscue,	Francis Ashbel Pomeroy,
Henry Tuthill Hallock,	Archibald Adams Reid,
Frederick Prepu Halton,	August Henry Ritter,
Eugene Franklin Hamburg,	Frank Wheeler Severn,
Patrick Hayden,	Oliver Cotton Smith,
Norman Harvey,	Alfred Burman Smith,
William Vincent Hazeltine,	Franklin G. Steele,
Charles Cincinnatus Henry,	Edward Marraanse Travers,
Walter Dennis Hough,	John Milton Williams,
Henry Clinton Hood,	Lucius Judson Woodworth,
Frederick Albert Jewett,	Charles Reid Whitcomb,
	Charles William Watt.

THE ST. LOUIS DAIRY COMPANY.

At a recent meeting of the St. Louis Medical Society, of which we find an excellent report in the "Weekly Medical Review," Dr. Coles read a most interesting paper on milk culture, in which he brought forward a number of important facts bearing upon the production of really good milk, and dwelt in a wholesome way upon the importance of milk as an article of food for infants and for invalids.

A point of practical interest in Dr. Coles's paper was, that he announced, and apparently with some confidence, that the St. Louis Dairy Company proposed to furnish pure milk in good condition. We take it that the company is a new organization, and we trust that it will not recede from the policy thus put forward. Certain it is that it is on the vigilance of the large towns that we must depend in this matter, for the bucolic mind still clings to the notion that city people are grossly incompetent judges of milk.

GAILLARD'S MEDICAL JOURNAL AND THE NEW-CODE MEN.

"GAILLARD'S MEDICAL JOURNAL" lately criticised the advocates of the new code severely for professing to act from lofty motives, whereas, it hinted, their mercenary motives were plainly shown by their frantic endeavors to prevent the publication of their names, which publication had been called for by a correspondent of the "Louisville Medical News," in order that Western physicians might know whom to avoid in sending patients to New York for advice and treatment. The article

in "Gaillard's Medical Journal" was headed, "A Strange Inconsistency." We reproduced it in our issue of May 26th, and added that there did appear to be some inconsistency, seeing that the same number of "Gaillard's Medical Journal" contained the list alluded to.

We regret to see that our excellent contemporary falls into the error of supposing that we intended to characterize as an inconsistency its action in publishing the "appeal" of the new-code men in the same issue with its vigorous denunciation of their course. "Such liberality," it justly and courteously adds, "the *New York Medical Journal* should be the last to condemn as it has certainly displayed this proper spirit in its own course." The inconsistency that we really had in mind was that of accusing the new-code men of shrinking from publicity, and at the same time publishing a list of their names, furnished, as everybody knows, by themselves.

THE MEDICO-LEGAL JOURNAL.

We have received the first number of this new quarterly publication, dated June, 1883. It contains the inaugural address of the president of the Medico-Legal Society and a number of other articles of interest. The number contains 118 pages, and makes a creditable appearance, being embellished with an excellent steel-plate likeness of the late Dr. George M. Beard.

NEWS ITEMS.

THE ERIE COUNTY COMMITTEE ON LEGISLATION.—The committee called for by the resolutions lately passed by the Medical Society of the County of Erie, which will be found in our Buffalo letter, consists of Dr. John Hanenstein, Dr. M. D. Mann, Dr. F. S. Crego, Dr. Edward Storck, Dr. A. R. Davidson, Dr. H. R. Hopkins, and Dr. A. H. Briggs.

YELLOW FEVER AND SMALL-POX IN HAVANA.—The National Board of Health is reported to have information that there were eighty-one deaths from yellow fever in Havana during the month of May, of which ten were among private individuals, and the remainder among members of the army and navy in the military hospital. The disease was slowly increasing in Havana, particularly along the wharves, and mercantile vessels moored near the military hospital had been invaded by it. There were also four deaths from small-pox in Havana in May.

TWO TRAVELING QUACKS.—The Mayor of Philadelphia lately received a letter from St. Paul inquiring whether Dr. H. W. Darling and Professor A. Campbell, M. D., were connected with the Philadelphia Dispensary. The letter stated that these two men were traveling through the Western States representing themselves to be the founders of the dispensary. Inquiry at the dispensary showed that no such persons were in any way connected with that institution.

AN HONORARY DEGREE.—Haverford College has conferred the degree of doctor of laws upon Dr. Thomas F. Cock, of New York.

A NEW OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.—According to the "Medical Times and Gazette," Dr. G. Ernest Herman has been appointed to this position, and to that of lecturer on midwifery in the school, in place of the late Dr. Palfrey.

A BANQUET IN HONOR OF M. VILLEMIN.—We learn from the "Union médicale" that, at the suggestion of M. Verneuil, a dinner was recently given in Paris in honor of M. Villemin, as a reminder of the credit due him for investigations that first established the infection doctrine of tuberculosis.

Proceedings of Societies.

AMERICAN NEUROLOGICAL ASSOCIATION.

The ninth annual meeting was held at the hall of the Academy of Medicine, New York, June 20, 21, and 22, 1883.

First Day—Wednesday, June 20th.

The association was called to order at 2.30 p. m. by the retiring President, Dr. WILLIAM A. HAMMOND, of New York, who, in a few well-chosen words, introduced the President-elect, Dr. R. T. EDEN, of Boston.

THE PRESIDENT'S ADDRESS.—The President, in his address, said that progress in this department of medicine had related chiefly to cerebral localization. Certain tendencies to error in deduction in neurological study were alluded to, and trustworthy methods of investigation were suggested.

A letter was read from Dr. E. C. SEGUIN, regretting unavoidable absence, and resigning the secretaryship.

The following gentleman were elected members of the association: Dr. L. Weber, of New York; Dr. G. S. Walton, of Boston; and Dr. J. T. Eskridge, of Philadelphia.

Dr. R. W. AMIDON, of New York, was elected secretary *pro tem.*, and then read his annual report.

ELECTION OF OFFICERS.—Officers for the coming year were elected as follows: President, Dr. Isaac Ott, of Easton, Pa.; Vice-President, Dr. W. R. Birdsall, of New York; Secretary and Treasurer, Dr. R. W. Amidon, of New York; Council, Dr. V. P. Gibney and Dr. W. J. Morton, of New York.

THE LATE DR. BEARD.—Dr. C. L. Dana and Dr. C. K. Mills were appointed to draft resolutions in regard to the death of Dr. George M. Beard, of New York.

NEURITIS FOLLOWING DISLOCATION AT THE SHOULDER was the title of a paper read by Dr. W. J. MORTON, of New York. The case referred to was that of a man, sixty-five years of age, who fell and dislocated the right shoulder. The dislocation was reduced at Bellevue Hospital, and the patient was discharged on the second day. The following condition of things was found afterward to exist in the right hand and wrist: Pain and swelling; the skin glazed, mottled, cold, and adenomatous; the nails club-shaped; the joints of the limb painful; impairment of motion, neuro-muscular super-excitability. Afterward there was a transfer of these symptoms to the opposite member. The treatment consisted in the application of electricity, a blister over the tract of the brachial plexus, hot and cold douches, and the use of cod-liver oil. Dr. Morton considered the case one of neuritis, commencing in the injured brachial plexus, and ascending to the spinal cord; hence the transfer of symptoms to the left arm. The case, as would readily be recognized, presented several interesting and perhaps unique points. The usual result of neuritis was atrophy of the tissues supplied by the affected centers. He had found record of but a single case in which hyperplasia instead of atrophy had taken place, namely, that of Dr. S. Weir Mitchell. The condition of neuro-muscular super-excitability resembled the *Myoclonus* described by Charcot, and the patient, it was suggested, had been best to meet the present case.

The paper was discussed by Dr. PUTNAM, Dr. MILLS, Dr. GIBNEY, Dr. WEBER, and Dr. HAMMOND. Dr. WEBER, speaking of treatment, had not produced benefit in similar cases from electricity, but had found decided benefit from blisters.

Dr. HAMMOND advised complete rest of the affected nerves and their centers; and, to a compass that, he proposed nerve-

stretching. Electricity did harm by excitation. Dr. PUTNAM applied ice.

NOTE ON HYDROBROMIC ACID AS A SUBSTITUTE FOR THE BROMIDES.—This was the title of a paper read by Dr. C. L. DANA, of New York. The dose of the pure acid should be from ten to twenty drops; of the official, or the ten-per-cent. solution, one drachm to two drachms and a half. It was usually given in two small doses. During the past two years he had employed hydrobromic acid in the following conditions: Epilepsy, alcoholism, various forms of headache, vertigo, general nervous depression, neurasthenia, chorea, insomnia, hysteria, post-hemiplegic disturbances, etc. He had seen the greatest benefit from the drug in epilepsy, in post-hemiplegic difficulties, and in other lighter general nervous troubles. It did not prevent cinchonism, certainly not in the small doses in which it was usually prescribed. Hydrobromic acid was recommended in preference to the haloids, because it was agreeable to take, non-irritating, and did not produce an eruption or bromism.

Dr. HAMMOND had found the haloid salts more effective in nearly or quite all conditions in which the bromides were indicated. He had employed only the weaker, or Fothergill's, solution of hydrobromic acid, and, contrary to Dr. Dana's experience, it had prevented cinchonism, although bromide of potassium was more effective.

Dr. ESKRIDGE said that hydrobromic acid seemed to fill an indication in typhoid fever. Morphine was most effectual in preventing the disagreeable effects of quinine.

LEAD POISONING SIMULATING OTHER FORMS OF DISEASE.—A paper was read by Dr. J. J. PUTNAM, of Boston, in which the author related eight cases, most of them resembling different forms of chronic and sub-acute myelitis, but afterward proved, by examination of the urine, of the gums, and by other facts, to be cases of lead poisoning. One case simulated cerebral disease. Certain sources of error in the detection of lead in the urine were pointed out.

A CASE OF GENERAL NEURALGIA.—Dr. J. T. ESKRIDGE, of Philadelphia, related the case of a man, twenty-nine years of age, rather stout, nervous organization, without venereal history. Father had died of some spinal trouble. The patient's health was good until 1873, when he had a slight attack of pneumonia. Soon afterward there was pain in the spinal region, and later along the line of the left sciatic nerve; locomotion was very difficult. From this time up to the present the patient had suffered from neuralgic symptoms in various nerves, and finally in nearly all of the sensory nerves of the body, at intervals varying from one to two months. The left facial nerve and the right leg escaped. At one time the temperature of the left leg was from one degree to one and a half higher than that of the right or unaffected side; the temperature of the affected side was at one time notably elevated. There was no affection of the nerves of hearing and of sight; the taste of sugar was imperfectly recognized on the left side of the tongue. The patient grew worse under anti-syphilitic treatment. Various remedies usually vaunted in the treatment of sciatica and rheumatism failed to give relief. Temporary benefit was derived from perfect rest in bed, and from alternate hot and cold douches to the spine. Lately boils had developed over various portions of the body. The question of diagnosis was uncertain; polio-myelitis, myelitis, syphilis, and general neuralgia each had been suggested.

Dr. WEBER, of New York, related a similar case, occurring in a man forty-five years of age, in whom he made the diagnosis of polio-myelitis, a number of cases of which had been reported by German physicians, and had been successfully treated. The present case was completely cured in two weeks by dry cups

along the spinal column, ergot, and bromide of potassium. He looked upon the case narrated by the author of the paper as one of lepto-meningitis.

Dr. ESKRIDGE thought that, if the case were one of lepto-meningitis, the electrical current would cause pain, which it did not.

A CASE OF LOCOMOTOR ATAXIA TERMINATING AS GENERAL PARALYSIS OF THE INSANE was the title of a paper read by Dr. C. K. MILLS, of Philadelphia. The patient was a man, forty years of age, of strong constitution, until about eight years ago, when he began to suffer from symptoms pronounced to be rheumatic, for which he continued to be treated for three years. There had been chance, but no secondary or tertiary symptoms had manifested themselves. The patient was addicted to venereal excess and to alcohol. A detailed description was given of the symptoms of locomotor ataxia, which developed gradually and became typical, and then passed on, after about four years, to present typical symptoms of general paralysis of the insane. The patient died eight years after the commencement of so-called rheumatic symptoms. A minute microscopical examination was made. Throughout the spinal cord there was marked sclerosis, more marked in the lumbar region; also inflammation of the pia mater throughout. There was sclerosis of the pons, of the optic thalami, and of the cerebral convolutions examined.

Dr. MILLS then reviewed the literature of the subject, and presented the views of various authors with regard to the possible etiological relation between the two affections named occurring in the same patient, and stated that while at first he was inclined to the view that there had been a direct extension of the sclerosis from the lower portion of the spinal column upward, until it had reached the cerebral convolutions, he was at present rather of the opinion that the condition involved the various portions of the cerebro-spinal system separately, and not necessarily by direct extension from the starting point. He believed that some cases began as a low grade of chronic meningeal trouble, or peripheral perineuritis.

The paper was discussed by Dr. SHAW, Dr. BREDSALL, Dr. WEBER, Dr. MORTON, and the author. The discussion of Dr. Putnam's paper, having been postponed, was now taken up, and was participated in by Dr. WEBER, Dr. MILLS, and the author.

REMARKS ON THE ALLEGED RELATION OF SPEECH DISTURBANCE AND THE PATELLAR TENDON REFLEX IN PARETIC DEMENTIA.—Dr. E. C. SPITZKA, of New York, began by referring to a paper read by Dr. J. C. Shaw, in which he maintained that there was a relation between speech disturbance and the abolished tendon reflex in general paralysis of the insane. Dr. Spitzka remarked that on *a priori* grounds this view seemed to be as startling as that of Austin, who asserted that the pupils differed according to the delusions, whether expansive or depressive, in the same disease; and, even if it were true, it would require a hundred-fold more proof to establish it than the referring of a certain cortical phenomenon to a cortical area, or a spinal function to a spinal segment. Of course, the tendency in science was toward so assigning functions, while nothing could be more remote than the lumbar enlargement of the cord from the tendon-reflex area and the speech centers, unless it were the frænum terminale from the olfactory bulb. Eighteen cases were read, the majority of which conflicted with the theory.

The paper was discussed by Dr. SHAW, Dr. PUTNAM, and the author.

(To be continued.)

NEW YORK SURGICAL SOCIETY.

A STATED meeting was held May 22, 1883, T. M. MARKOE, M. D., President, in the chair.

AN EXTREMELY COMPLICATED CASE OF CIRCUMSCRIBED CONTRACTION FROM BURNS.—Dr. ALFRED C. POST read a paper with this title [see page 682], and showed the patient.

Dr. H. B. SANDS said he had operated twice for the relief of contraction of the fingers caused by a burn of the palmar surface of the hand, and in both cases he had had the advantage of Dr. Post's counsel and assistance. He performed operations similar to those which had just been described, and was surprised to find how freely the cicatricial tissues could be divided without causing mortification. In both of these cases it was necessary to resect several of the joints in order to bring the fingers into a straight position. Subsequently the fingers of those joints which had been resected were considerably shortened; still, their position was very much improved. He had noticed that where resection had been made motion was destroyed, and he would like to ask Dr. Post if he had succeeded in restoring any amount of motion in these resected joints.

Dr. Post replied that absolute rigidity had been prevented, and that it was rather desirable that very free motion should not be established, because there are no lateral ligaments, and free motion could not be established without making the movements of the fingers wabbling or fail-like.

The PRESIDENT asked if in exsection the head of both bones was removed.

Dr. Post said that only the distal end of the proximal bone was removed.

The PRESIDENT asked if Dr. Post proceeded in the same way for contraction of the palmar fascia.

Dr. Post replied that he performed substantially the same operation. He also thought that Mr. Adams, of London, was in error in speaking of Dupuytren's contraction as being always due to gout, as he had seen it arise from a variety of traumatic causes.

Dr. G. A. PETERS said he had recently had a case in which this contraction was brought about by rolling.

Dr. Post remarked that in traumatic cases the integument was firmly adherent to the fascia, and in the cases which he had seen it was not an easy matter to make the incisions without dividing the fascia.

The PRESIDENT said that he had recently seen two cases with Dr. Abbe, who performed the operation described by Dr. Post, and he was surprised at the moderate amount of inflammation which followed the multiple incisions.

Dr. PETERS asked how long counter-extension was maintained.

Dr. Post said sometimes two or three months, alternating with passive motion. He further remarked that there was a curious feature in all cases of cicatricial contraction, and it was that the parts having been bound down, the process of restoring them to their original position by passive motion is very painful.

INTESTINAL OBSTRUCTION.—Dr. SANDS presented two specimens, removed from the body of a man on whom he had performed the operation of inguinal colotomy for the relief of intestinal obstruction. As would be remembered, in the month of March, 1882, he exhibited this patient to the society three weeks after the operation. It would be remembered, also, that the patient had had a fecal abscess to the left of the median line in the umbilical region; that the abscess had closed, and that coincident with the closure of the abscess there appeared signs of intestinal obstruction, which were complete at the time when colotomy was performed. The operation gave entire relief, and the man was able to be about for nearly one year. It

was noticed, however, that during all this time he was exceedingly harassed by an inability to control the artificial opening. This opening was not more than one third of an inch in diameter, but no form of bandage or truss had any effect in preventing the feces, which came from the opening. Owing to this infirmity, he was prevented from pursuing his occupation. Dr. Sands lost sight of the patient for a long time, but finally heard that he was again suffering from intestinal obstruction. When he saw him he found that the escape of feces from the artificial anus was imperfect, and he therefore enlarged the opening somewhat by the use of sponge tents, giving considerable relief.

On the 15th of April last the patient died, and an autopsy was made on the following day. Death resulted from peritonitis, the cause of which did not seem to be quite clear, although most probably it was due to inflammation occurring at the site of the previous abscess. On opening the abdomen, the coils of intestine were found almost everywhere adherent; recent lymph, mixed with sero-purulent fluid, covered the surface of the intestines, and the pelvic cavity contained a certain amount of turbid fluid. No gas escaped when the cavity was opened, and there was no reason to believe that the peritonitis had been occasioned by perforation of the intestine. The site of the previous abscess was found to be the seat of a phlegmonous inflammation apparently on the verge of suppuration, while opposite to this the large intestine was found firmly adherent to the abdominal wall, the part attached being the descending colon a short distance above the sigmoid flexure. There was also noticed a very firm adhesion between this part of the descending colon and a segment of the small intestine, which subsequently proved to be the jejunum. The large intestine above the sigmoid flexure was enormously distended. The diameter of the distended gut was not measured, but was estimated as being three or four times the normal caliber. This distension extended from the cæcum to a point very near to the sigmoid flexure, where the occlusion of the large intestine was complete. A segment of the abdominal wall was removed corresponding with the site of the adherent large intestine, which was also removed, together with a piece of the small intestine.

It was noticed that the feces contained in the large intestine were remarkably soft; such as are commonly found in the small intestine.

In the large intestine below the point of complete occlusion was found a small amount of feces of firm consistency and dark color. The artificial anus was found pervious, the opening being about one fourth of an inch in diameter, and it seemed difficult to understand why the feces did not escape from it. A portion of the abdominal wall corresponding to the site of the artificial anus was also removed. The two specimens were presented. The first consisted of a portion of the large intestine adherent to the abdominal wall, a portion of the integument, and a piece of adherent small intestine. The most interesting point connected with this specimen was the presence of a large opening, oval shaped, and one inch in diameter, leading from the colon into the jejunum. Besides this, there were two abnormal channels, one narrow fistulous tract starting from the large intestine adjacent to the opening which led to the small intestine, and passing through inflammatory products to a point in the large intestine about an inch below the point of complete obstruction. Just above the complete obstruction there was also a small opening into the small intestine, forming a channel, communicating with the small intestine.

The second specimen consisted of a portion of the large intestine, showing the site of the artificial anus. The operation had been performed by cutting through the peritonæum. Pains were taken not to examine too thoroughly the contents of the abscess, and

Dr. Sands opened the distended intestine, not knowing precisely what it was, but he believed it to be the cæcum, from the size and position of the gut, and from the fact that it seemed to be fixed to the posterior abdominal wall. The specimen showed that the opening was made into the front wall of the cæcum, near the lower wall of the cul-de-sac. The mucous membrane of the cæcum and the vermiform appendix were considerably thickened, but beyond this no abnormal changes were noticed.

It was interesting to consider what the course of the fæces must have been in this patient during life. Instead of passing, in the usual manner, through the entire length of the small intestine, they must have been diverted, to a great extent, through the large opening already described, into the large intestine just above the juncture of the descending colon with the sigmoid flexure. Being prevented from passing downward toward the anus, they must have traversed the colon in a backward direction toward the cæcum. The ileo-cæcal valve being shut, and the artificial anus very narrow, distension of the colon naturally followed, although it seems as if this might have been relieved by dilating the artificial anus, and by the use of enemata.

Perhaps it was in consequence of the fact that the fæces did not traverse the small intestine that the general condition of the patient deteriorated, leading to rapid emaciation. When the large opening between the large and the small intestine was established it was impossible to say, but it was plain that the fecal abscess was connected with the large intestine, because no neoplasm was found in any part of the abdominal cavity; nor was any foreign body found in the discharges at the time of the opening of the abscess which could explain the perforation.

Whether the two perforations—that of the large intestine toward the external surface, and that of the large intestine toward the small intestine—had the same cause, namely, follicular ulceration of the large intestine, could not be stated, but this was rendered possible by the several lesions of the large intestine.

The case was remarkable in the fact that an abscess allowing of the escape of the entire fæces should close spontaneously in spite of complete occlusion of the sigmoid flexure, and then give rise to symptoms which required the formation of an artificial anus.

Examination of that part of the mucous membrane of the large intestine which corresponded with the site of the former abscess showed no cicatricial tissue to mark the previous existence of an ulcer in that situation.

The other lesions found were fatty liver with commencing cirrhosis, and a cyst in one of the kidneys, without any other evidence of renal disease. The man was fifty-nine years of age at the time of his death.

The President remarked that not infrequently tubercular ulcers perforated the wall of the intestine, and afterward the fæces found their exit through another part of the intestine, perhaps far distant from the original point of rupture. But in the case reported by Dr. Sands there was no evidence of tubercular ulcers. The President had one case, that of a young lady, suffering apparently from tuberculosis, in which the duodenum opened into the colon, and the patient perished simply from lack of nutrition, and with evidence of peritonitis extending over weeks and months.

Dr. C. K. BRIDGON had an impression that diseases of similar character were not infrequent among colored people. He recollected that the late Dr. Whitall expressed to him that opinion, and showed him a case where an abscess of the abdominal walls was followed by a fistulous communication of the intestines with stercoral ulcers resulting in abscess, and stated that these cases were not uncommon, but that they were always

fatal. Whether such ulcers were tubercular or not he was not prepared to say.

Dr. PEREZ thought they probably were.

Dr. BRIDGON had under observation a patient who was admitted to the Presbyterian Hospital with a sinus at the umbilicus, giving exit to flatus and fluid fæces. He was unable to obtain any history of diarrhœa or of dysentery, or very much pain, and, on examining the abdominal walls, the only spot of induration was in the middle line, between the umbilicus and pubes. That led him to make a vaginal examination, and he found a swelling in Douglas's cul-de-sac, but he was unable to make out whether it was the result of infiltration or was a retroverted uterus. The retroverted uterus could be made out, but the mass seemed to be too large for that condition alone. He was able to introduce a sound four or five inches into the fistulous track, and he believed that it passed directly into the intestine.

Dr. POST said that a number of years ago he reported a case to the Pathological Society, that of a gentleman who was thrown from a buggy in Central Park, and received a severe contusion in the loins which led to the formation of an abscess with which the descending colon communicated, and for the remainder of his life he passed his fæces through this fistulous opening. On examination of the body at the autopsy, he found quite a close stricture which had interfered with free evacuation of the bowel in either direction. The greater part of the fæces passed through the fistulous opening, and always where there was solid matter it passed with pain and difficulty. He thought that probably free colotomy would have benefited such a patient.

Dr. BRIDGON asked Dr. Sands whether he regarded the difficulty which his patient experienced in retaining fæces depended upon the location of the artificial anus or upon the fluid condition of the fæces from the communication with the small intestine.

Dr. SANDS said that he did not know, but he imagined that it depended considerably upon the situation of the artificial anus, and he should regard this as a great drawback to the operation of inguinal colotomy.

Dr. BRIDGON remarked that he had not seen a case in which the patient experienced any trouble in retaining fæces after lumbar colotomy.

ACUTE OSTEOMYELITIS FOLLOWING SLIGHT INJURY OF THE ANKLE.—Dr. CHARLES MCBURNEY presented the leg and foot removed a few days since from a child nine years of age, which illustrated how extensive might be the damage done by a neglected periostitis. Two months ago the child, while jumping the rope, struck the ankle with the other foot, which gave her extreme pain and caused her to fall. Curiously enough, the child was allowed to go to school on the next day, and continued to do so for four weeks, but at the end of that time the pain and suffering were so intense that a physician was sent for, who regarded the case as one of cellulitis, and treated it as such by the application of poultices, subsequently made some incisions, and gave vent to a large quantity of pus. The case, however, did not progress favorably, and, consequently, Dr. McBurney was invited to see it in consultation. He found the foot exceedingly œdematous, and also the leg up to the knee, and the skin was covered with blebs. The child's general condition was very bad; there was alternating high and low temperature, with sweats, etc. Quite a large granulating orifice on the inner aspect of the limb, and a similar one on the outer aspect. There was evidence of extensive denudation of bone, and the epiphysis of the tibia at the ankle was separated. The joint was opened; the articular cartilages were more or less destroyed. Dr. McBurney amputated the limb at the middle of the leg, closed the wound

with carbolized silk sutures, powdered it with iodoform, inserted a drainage tube at the lower angle, and applied a peat dressing over the whole. The temperature had not risen above 99° F. since the operation. Previous to that it fluctuated between 99° and 102°, accompanied by sweats and general constitutional disturbance. The dressings had been changed at intervals of varying length, the first being allowed to remain five days, at the end of which time the drainage tube was removed, and the progress of the case thus far had been eminently satisfactory.

URINARY CALCULI.—Dr. BRIDGON presented specimens, and related the history of a case as follows: On Sunday afternoon he was called to the Presbyterian Hospital to see a child two years old, who had suffered eight or nine months ago from an attack of abdominal pain which had been called renal colic. Since that time he had had frequent attacks of pain, frequent micturition, and a disposition to pull upon the prepuce. Two or three days before admission he had an attack of retention of urine, which was relieved by the catheter. On the night before admission he attempted to empty a distended bladder, but only with partial success. On the afternoon of the day of admission the bladder was distended up to the umbilicus, and the house surgeon attempted to introduce a catheter, but found an obstruction about three inches from the meatus, which he was unable to overcome, and the bladder was then aspirated. Dr. Bridgdon saw the patient at nine o'clock in the evening, passed a silver catheter, No. 6, down to the obstruction, and without material difficulty succeeded in introducing the instrument into the bladder and emptied it. The child's temperature that night was 106° F., a fact for which he was not able to account. On the following day the temperature was 105° F., and the bladder was again distended. He introduced an instrument into the bladder, encountered an obstruction, but whether it was in the prostatic portion of the urethra or in the bladder, he was unable to say positively. He performed median lithotomy, encountered no obstruction in entering the bladder, readily came upon the smaller of the two calculi presented, which was exceedingly minute, and removed it. He then withdrew the staff, introduced the finger, and found the large calculus lying in the incision; probably it was the calculus which had been impacted within the urethra, and it was about five sixteenths of an inch in diameter.

Dr. BRIDGON also presented a specimen of the same character, which he obtained in 1861. He was called to visit a child two years and seven months old, who was suffering from retention of urine. He introduced a catheter, detected a small calculus, but found no difficulty in drawing off the urine. On the following day he was about to proceed to remove it by lithotomy, and as soon as he drew the prepuce down he found a small calculus impacted in the meatus, about half of it projecting, and it was easily removed. After its removal he introduced a sound into the bladder, and detected a large stone, which he removed by the lateral operation.

He was unable to explain the high temperature which occurred with the retention of urine in his first case.

Dr. POST remarked that retention of urine was a cause for considerable constitutional disturbance, and probably of itself would explain the elevation of the temperature.

Dr. BRIDGON thought it unusual for retention to be associated with such a high temperature.

DISLOCATION OF THE HEAD OF THE FEMUR IN ACUTE RHEUMATISM.—Dr. C. T. POORE narrated a case as follows: On Tuesday last he was called to see a boy, seven years of age, who had had inflammatory rheumatism for four months. As a result, there was contraction of both knees, and the left thigh was flexed and adducted considerably. On examining the limb very care-

fully, he found that the head of the femur was dislocated upon the dorsum of the ilium. He thought that there was no doubt but that it was a case of acute rheumatism, and that the hip had been out for at least six weeks. The dislocation was reduced, but it recurred. He proposed to divide the tendons and place the patient in a fixed apparatus. The acute attack of rheumatism involved both knees and the left hip, which was the one that was dislocated, and also the elbows.

The PRESIDENT said it would seem that such a dislocation could not occur without some change in the acetabulum. The inference would be naturally that there was some coxitis present.

Dr. POORE said that he thought there was no doubt but that it was a case of imple acute rheumatism. There certainly was no evidence of morbus coxarius. Further, the hip joint has been known to be dislocated in acute diseases—for example, in typhoid fever, a case of which was recorded last year in one of the Liverpool journals.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

A REGULAR meeting was held May 28, 1883, the President, DAVID WEBSTER, M. D., in the chair.

THE LOCAL USE OF ANESTHETICS AFTER LABOR AND ABORTION.—Dr. W. GILL WYLIE read a paper with this title [see p. 679].

In the discussion, Dr. PAUL F. MUNDÉ said that for several years he had had most positive convictions on the subject, and had followed a decided practice in the treatment of puerperal septicæmia. Since Dr. Chamberlain introduced the long glass tube known by his name, he (Dr. Mundé) had made it a rule to inject every puerperal uterus as soon as the temperature rose above 102° F., whether the lochia became offensive or not. He continued these intra-uterine injections (of a two-per-cent. solution of carbolic acid) three or four times daily until the temperature was permanently lowered, or until their inefficiency became evident. He had thus repeatedly reduced the temperature from 105° to 102°, from 103° to 98°, and the pulse in proportion. He had seen the temperature remain down after a while—but, again and again, he had seen it go up, and finally stay up, in spite of the injections. It was true, he had not repeated them so often as Dr. Wylie had done, and perhaps his occasional bad results had been due to this fact. In future he would certainly follow Dr. Wylie's plan in intractable cases.

But he would like to direct attention to the fact that in all cases of puerperal septicæmia there was a time when intra-uterine injections not only did no good, but were even positively injurious, viz.: 1. In cases where the lochia were not at all offensive, and the seat of infection seemed already to have spread to the parametric tissues, and to lie beyond the reach of intra-uterine medication. 2. Where the injections had been used faithfully for a period of from forty-eight to seventy-two hours, with little or no benefit—certainly no lasting benefit. In both these sets of cases the disease had already advanced beyond the scope of local remedies, and in those of the second category the injections even seemed to provoke a traumatic rise of temperature; he had known the frequent introduction of the tube, and the injection of medicated fluids, to do harm, and to be followed by more or less septicæmia. But as a treatment of puerperal septicæmia, or indeed in any case where there was a rise of temperature, especially if the lochia were fetid, his first step was to wash out the uterus, repeating it as often as the temperature seemed to require; and the results in many cases had been so surprising, so successful, and so beneficial as to make him feel the greatest confidence in the treatment. In a few cases, it was true, it had failed, but those were mostly cases to which he had been called in consultation at a late period in their course. In the very few cases in which the lochia had been fetid and yet the patients had recovered, the salicylate of sodium, in ten-grain

doses every two hours or oftener, had seemed to produce a permanent reduction of temperature, followed by recovery, even after failure with the largest doses of quinine.

Dr. MALCOLM McLEAN was a strong advocate of the practice of intra-uterine antiseptic washings, as recommended in the paper, but considered it necessary to repeat them oftener than every three hours. He thought the paper did not lay stress enough upon the necessity of guarding against the dangers of intra-uterine douches, which were: 1. The danger of forcing fluids through the Fallopian tubes into the peritoneal cavity, producing profound shock, and possibly peritonitis. 2. The introduction of air into the uterine sinuses. To avoid these accidents, he urged the importance of using a *continuous* stream, like that from the fountain syringe, and not an interrupted one: and the stream should be flowing *before* the tube entered the uterine cavity. It was best to use a soft catheter. Accordingly, he could not agree with the reader of the paper that it was good practice to leave an empty tube in the uterus for injections to be given through at intervals—possibly by a nurse. The operation was sufficiently important to be done by the physician only.

In cases of septic absorption after early *abortions* it was difficult to use a good-sized tube and allow free exit to the fluid alongside. In such cases he had found the practice of wiping out the uterus with a strong solution of carbolic acid in glycerin, by means of a cotton swab, an easy, safe, and efficient method of thoroughly cleansing the uterine cavity.

He believed that many failures to reduce alarming temperatures in septic cases after labor were credited to intra-uterine douching, when in fact only vaginal douches had been used. He added that his remarks were all based upon an earnest study of the subject in his own practice, and upon the reports of very trustworthy and capable observers; the dangers he had alluded to had been demonstrated in his own experience.

Letters to the Editor.

THE CODE QUESTION.

NEW BRIGHTON, N. Y., June 3, 1885.

To the Editor of the New York Medical Journal:

SIR: I have no desire to add to the futile discussion of the respective merits or demerits of different "codes"; but, from the standpoint of that "personal liberty" which is the alleged basis of the State society's recent action, an inquiry concerning the position of the non-political private practitioner seems to be in order.

In a paper on the Status of the Medical Profession, in your issue of June 2d, I find the following statements:

First, that "the State society, with perfect deliberation, and with its eyes open, resigned from the American Medical Association"; and that this action was taken by the "large vote" of "fifty-two to eighteen."

Second, that those who have incited the various county societies to the "seditious action" of determining for themselves whether or no they will adhere to the pre-existing code are "apparently unaware that such action by the county societies would be absolutely null and void"; and that the said county societies may be assured that the code which has always hitherto ruled them "can not be of any other use to them, except, perhaps, to beguile the American Medical Association into admitting them to representation."

Thirdly, that "the propriety of instructing delegates" from the county societies to vote in accordance with the sentiments of their constituents "is open to question."

I am not—not have I any ambition to be—a member of the State Medical Society (which I have heretofore regarded as a purely representative body, like a State legislature, instituted to embody and carry

out the views of its constituent county societies as represented by their delegates), but I am a member of a county society which, from its inception, has made acquiescence in the national code one of its conditions of membership. It appears now, however, that my fellow-members and myself (with the one independent exception of our delegate) can have no opinions of our own touching our rules of professional conduct, but that we must change our views of right and wrong at the bidding of fifty-two gentlemen, to whom, howsoever much we may admire their personal characters and professional attainments, we have never deputed control over our consciences. The constitution and by-laws which were approved by the State society up to last year must be reversed at their behest (and, for all we can foresee, may have to be altered annually hereafter) under pain of discipline for sedition.

If fifty-two gentlemen, however conscientious be their deliberations, can not only resign their own connection with the national medical association, but carry with them, *volens volens*, all the county societies of the State, comprising some thousands of practitioners, there is virtually established an oligarchy which, in principle, appears more objectionable than the alleged tyranny of the American Medical Association. Even in larger numbers, if uninstructed delegates, misrepresenting their constituents, and permanent members, representing no constituency at all, can agree upon such wholesale "resignation," their action seems analogous to that of a State legislature which should pass a secession ordinance, regardless of the sentiments of the voters at large. In either case, the autonomy of the local societies—the only organizations really representing the mass of the profession—is set at naught; their action, or, rather, inaction, in conserving the rules formerly declared necessary for their existence is pronounced null and void; and the great multitude of home-staying practitioners are reduced to the condition of mere puppets, without even a reasonable excuse for expressing their preferences through their few delegates to Albany.

I am, sir, yours, etc.,

ALFRED D. CARROLL.

THE AMERICAN MEDICAL ASSOCIATION.

NEW YORK, June 14, 1885.

To the Editor of the New York Medical Journal:

SIR: Your courtesy on two former occasions, in allowing me to express through your columns views at variance with your own, emboldens me to presume once again; this time, however, not for commendation, but for complaint.

The American Medical Association, for which I entertain sentiments of respect and admiration, in which I can not suppose you fully sympathize, has disappointed me sorely in the selection of its presiding officer. I did expect that at this time, above all others, when interest in regard to ethical matters is at its height, the association would have chosen for its president a man whose loyalty to its code as it stands, *verbatim et literatim*, would be above suspicion. This it has failed to do.

It is scarcely more than a month since Dr. Flint, through the columns of your own journal, labored to break down the force of the restrictive clause in the code, and concluded by saying: "It is to be hoped that the American Medical Association will adopt such modifications in the phraseology of this section as will place restrictions on consultation, not on the ground of doctrines or forms of belief, but on separation from and avowed antagonism to the medical profession." Now, when it is remembered that, on the ground of doctrines and forms of belief, we thrust the homœopaths neck and heels out of the profession, and ourselves created the "separation" and "antagonism," I submit that Dr. Flint does not leave us a visible leg to stand upon. Heaven save us from our friends!

But I am glad to see that Dr. Flint has so far reconsidered his views as to be able to sign the required pledge to sustain the code as it is. I hope there is in this case none of that mental reservation referred to by Dr. Flint, Jr., at the Academy, and so ably exposed by Dr. Squibb in the article to which I called attention last week, and that we shall not be mortified next year by any movement toward a change. I am the more solicitous about this as I am informed that a great many joined the movement for re-enacting the old code in this State in the belief that our leaders would initiate some action in the asso-

ciation this year looking to revision. No expressions of disappointment or dissatisfaction to which these men may give utterance should be allowed for a moment to have weight with the association at its next session. The slightest concession now would be an evidence of pitiable weakness, and I trust that, whatever Dr. Flint's personal views may be, he will stand to the letter of his pledge.

It is exceedingly painful to me, Mr. Editor, to make these strictures; for I have the very warmest personal affection for Dr. Flint. But those of us who still smell the sulphurous atmosphere of the conflict of forty years ago can not renounce the feeling by which we were then actuated. In a moment of common peril private considerations must give way. It is not that I love Caesar less, but that I love Rome more. Our noble code claims the devotion of my heart, and when danger threatens it, personal friendship shall not deter me from lifting up my voice in its defense.

Yours very truly,

BOURBON.

THE PHYSIOLOGICAL EFFECTS OF NITRO-GLYCERIN.

TOMPKINSVILLE, N. Y., June 10, 1883.

To the Editor of the New York Medical Journal:

SIR: In the "New York Medical Journal," vol. xxxvii, page 662, in a foot-note, the "translator" asserts "that Field, in England, was the first to describe, twenty years ago, the physiological effects of nitro-glycerin."

Please insert the following in your journal as a correction:

In "Ze tschrift für homœop. Klinik," vol. ii, page 62, April 1, 1863—(THIRTY years ago!)—proving and cures with this drug are reported.

In "Amerikanische Arzeneiprüfungen," by C. Hering, M. D., Leipzig and Heidelberg, 1867—(TWENTY-SIX years ago!)—a treatise of this drug of 116 pages is published, which contains provings and cures. We find there that this drug was used in 1847, '48, and '49 by Carrol Danham, of New York city, Ohio, and other homœopathic physicians in the United States and Europe. *This was THIRTY SIX years ago!* ("Laëtic's" Journal" of the year 1851 cures are published. I myself experimented with it thirty years ago. You see that your translator is quite wrong and behind the times.

Yours respectfully,

G. OEHME.

THE MARINE-HOSPITAL SERVICE.

PHILADELPHIA, June 15, 1883.

To the Editor of the New York Medical Journal:

SIR: Dr. Hamilton's reply of the 21st ult., in your issue of June 2d, is not calculated to do "justice to the Marine-Hospital Service," nor to himself. He is, doubtless, pricked by his own conscience and the voice of the profession, rather than by the editorials of the "Medical Times," which are probably based upon the Treasury Reports and comments of the medical and secular press.

Dr. Hamilton states that he "simply replied to an assertion that it would be more economical to treat merchant-sailors in naval hospitals. He nowhere attacked the professional character of the medical corps, many of whom he numbers among his personal friends." Whose assertion? The assertion of a *midshipman*, which is not deemed worthy of a reply from the supervising surgeon-general? No one knew better than Dr. Hamilton that the Naval Medical Corps had nothing whatever to do with any proposed transfer of his department, and that it had no inducements to offer him nor his, as it was struggling to exist, and to retain a "bogus rank," which the law will neither acknowledge nor respect. It was, therefore, not anxious to increase its numbers and responsibilities, and yet he struck at this body—"many of whom he numbers among his personal friends." In the "Boston Herald" of the 20th of February, in that part of Dr. Hamilton's report characterized as "*picturesque*," the medical corps of the navy is assailed by an unworthy fling at its "flourishing (medical) society," and by other statements which drew forth a sharp reply on the 21st, from a medical officer of the navy who charges him with "dragging his attempt at argument through the dirt and slime of vituperation and abuse."

Referring to his report of January 5th, Dr. Hamilton appears to be in *doubt* (p. 34) about any intended transfer of the Marine-Hospital Service. To midshipman Alger, the author of all his woe, he deigns no reply, but pitches into the "aristocratic" medical corps, kindly suggests the "discharge of some of them," "some of whom he numbers among his personal friends"), and, after an odious financial and professional comparison between the two services (p. 39), and a self-glorification of his own work on the same point, he suggests the "discharge of supernumeraries," and closes up at page 52 with the astonishing statement that "it is not presumed that the common sailors entering hospitals ought to be subjected to the rigors of naval discipline, or that they should be put to bed at the point of the bayonet, and there is therefore no reason why the military should have especial and peculiar charge of this matter." It is unnecessary to follow the doctor further. Suffice it to say, that his own language will best convince the reader of his feelings toward the "medical corps, many of whom he numbers among his personal friends, and for whom, as a body of professional men, he entertains the highest respect."

ANOTHER MEDICAL OFFICER OF THE NAVY.

Miscellany.

THE ACTION OF CANNABIS INDICA.—In an article published in the "British Medical Journal," Dr. James Oliver, House Physician to the Hospital for Women, London, remarks upon the variable character of the effects produced by Indian hemp, and continues as follows:

"Two preparations of this drug have been recommended for use—viz., the tincture and the extract; it should matter little which is used, the tincture being simply a spirituous solution of the extract. Much, however, as far as results obtained go, seems to depend upon its place of cultivation. Many of those persons who experienced unpleasant effects from one-grain doses had previously taken the same dose (different sample, however) with almost no result at all. It is usually said that cannabis Indica produces pleasurable symptoms; such, I regret to say, has not been my experience; in fact, the result has frequently been alarming to the friends of the patient, but more frequently still, from the comparative inertness of the drug, no result is obtained at all, even although three and four grains have been given as a dose. When unpleasant symptoms have been produced by the use of this drug, they do not readily pass off, but will often persist for a day or two, and the too early use of morphia will not uncommonly aggravate the condition. The physiological effects of the drug usually manifest themselves about two hours after administration; this, however, varies, being hastened or retarded according to the condition of the stomach as regards food at the time of ingestion. Cerebral symptoms are the first to develop, the patient experiencing peculiar indescribable sensations in the head, by no means pleasant in character; and, although quite rational, knowing all that is going on, some have an irresistible desire to be always on the move. In some cases earlier, in others later on, the patient loses control over the muscles, being unable to move them at will; in one case the muscles of the larynx were so affected, and the patient, when interrogated, was for the time being unable to respond. Muscular anesthesia is often produced by the use of Indian hemp, and this is, as a rule, so complete that the whole body feels unsupported, as if floating in air. Pain, even at this stage, frequently persists, showing how little influence this drug evidently has on the sensory nerves. In some cases spasmodic contractions of the voluntary muscles result, and this is more especially to be noted in the muscles of the jaw. Dimness of vision in many cases quickly follows, the pupils in some remaining unaltered, in others being apparently contracted. The pupil responds to light, but accommodation is interfered with, objects at a distance being very indistinct. The pulse is invariably rapid, but quite regular. Sensibility to touch is unaltered. Numbness and tingling have been constant symptoms in all the cases."

KEFER, A NEW MILK FEEDING.—While, during the last six years, the milk has been introduced into western Europe and even into America,

says the "British Medical Journal," a new drink, prepared from cow's milk by a process of fermentation imperfectly understood, is coming into use in Russia. This drink is kefir, and it has for long formed the chief article of diet among the mountaineers in the neighborhood of Mount Elbruz and Kasbek, in the Caucasus. It forms a thick, white fluid, with a faintly acid flavor, said to resemble certain light wines. The mountaineers themselves call it "Ghippo." The inhabitants of the plains near the Caucasus, and the Russian settlers, who term it kefir, kifer, or khiafar, make use of it, not for the table, but as a popular remedy for anemia, struma, gastric catarrh, and chronic bronchitis. According to the Moscow *Medical Gazette*, where a contribution on the subject has recently appeared, Dr. Kern being the author, the preparation of kefir is very simple. The mountaineers make it by filling a bag made of goat-skin with milk, then a tenacious mass, of the size of a walnut, of a material which they term "kefir-seed," and the precise origin of which is unknown, is added to the milk. In a few hours the process of fermentation sets in actively. When prepared in wooden or glass vessels, the kefir tastes better. After a lapse of twenty-four hours, a weak kefir is produced; when the process is allowed to continue for three days, the kefir becomes very strong. The source of the ferment is scrupulously concealed by the Caucasian mountaineers, who, with the humor of the English cook, who once sold a secret for making "fun-dled cheese," the "secret" being that the cheese must be funded after t-asting and before the addition of pepper, can not be persuaded to enlighten strangers to any greater extent than in supplying a small sample of the ferment, in the form of dry, dark-brown, earth-like masses, but steadfastly refusing to say whence they are obtained. One of these fragments, dropped into milk, begins rapidly to effervesce, turns milk-white, and assumes the form of a mulberry; then fermentation proceeds at once. If a piece, thus transformed, be dropped into another bowl of milk, it rapidly increases in size, and also causes fermentation. Dr. Kern has carefully examined specimens of this "kefir-seed," which consists chiefly of masses of zoogloea, holding together collections of a bacterium which he calls *Dispora Caucasica*. The yeast-fungus, *Saccharomyces cerevisia*, is always found associated with this new germ. "Kefir-seed" retains its vitality after remaining for months in its dry condition. Dr. Kern has a great belief in the future of kefir, which has all the virtues of koumiss, and possesses one great advantage over the latter fluid in that it is just as good when prepared from cow's as from mare's milk.

LAUNDRIES AND INFECTIOUS DISEASE.—The danger of sending infected linen to the common laundry without previous disinfection, says the "British Medical Journal," must be obvious to any thoughtful person; but, like many other obvious things, this danger needs to be impressed again and again upon the attention of careless householders. A laundress may, unwittingly or otherwise, be both the recipient and the retailer of infectious particles; and to her powers of mischief in both capacities the following examples eloquently testify: Dr. Cameron, of Hendon, writes that laundries are a constant and prolific source for the introduction of small-pox, scarlet fever, and other diseases. Indeed, all the cases of scarlet fever and small-pox that occurred at Hendon during the past year were either introduced by persons coming into the district with the disease upon them, or through the medium of infected clothing being sent to be washed without previous disinfection. In September, scarlet fever was introduced through this medium, and thirteen children were attacked. Another outbreak in December seemed to emanate from one of the laundries, but, the children being at once isolated, the disease did not spread. Dr. Bruce Low, of Helmsley, in Yorkshire, has a remarkable experience to record. A young girl was hired to go to a house where there were two convalescents from scarlet fever, of which cases she was aware when engaged. A week after she went to her situation she contracted the disease, and was sent home as soon as the rash was discovered. No medical advice was sought, to avoid what her mother called "bother." This woman took in washing, and, as soon as the daughter was able to go about, she was sent out with the clean linen to the various houses. At one house, at least, the coppers received from the girl in change from the washing-bill were accompanied by large flakes of skin, which had peeled off the girl's hands. At the

house where the scales were received with the coppers and the linen there were subsequently several cases of severe scarlatinal sore throat. These facts were only traced some few weeks afterward; too late, of course, to prevent the mischief.

NOTES ON PARALDEHYDE.—Under this heading Dr. John Brown writes to the "British Medical Journal" as follows: "As I have prescribed this new drug on several occasions, it may be of interest to give my experience. The dose as a hypnotic is from thirty to fifty minims. It produces sleep in most cases in a few minutes after taking it, the effect lasting from three to seven hours. Larger doses, no doubt, would produce longer narcosis. It produces no headache, no constipation, nor stomach derangement, contrary to the report given of it. In one case it caused a slightly depressant effect on the heart. In a patient who had been accustomed to take chloral, it was stated that the sleep was refreshing, but, if disturbed during the sleep, the tendency to sleep left, which was not the case with chloral. Paraldehyde in some cases causes a peculiar burning taste in the mouth the following morning. The breath smells of the drug for several hours after waking. It is probable that nearly all the drug is got rid of by the lungs in the same state as it is taken. Paraldehyde is not much, if anything, superior to chloral. It costs five shillings per ounce; chloral, sixpence per ounce; besides which, it requires a larger quantity of the former, so that it is about sixteen times as dear as chloral. Therefore it is not likely to come into general use. Being so insoluble in water, it makes rather a large draught, which is objectionable."

A NEW METHOD OF TESTING FOR SUGAR IN THE URINE.—Dr. George Oliver, of Hargrave, lately read a communication before the Clinical Society of London on a new method of detecting sugar in the urine. "The principle of the test," says the "Medical Times and Gazette," "consists in the fact that by boiling saccharine urine with a solution of sulphindigotate of sodium, which has a blue color, a gradual succession of color-changes, passing in order from blue across the colors of the spectrum finally to yellow, takes place. The test can be carried about in the form of blue papers saturated with the indigo solution. The papers yield a clear, blue solution with distilled or fairly pure water. Indigo-blue in the presence of glucose becomes a colorless fluid: this was the circumstance which led Dr. Oliver to examine diabetic urine in this regard."

CEREBRAL VACUOLATION.—In a paper, by Dr. Hale White and Dr. Savage, lately read before the Pathological Society of London, a report of which we find in the "British Medical Journal," it was shown that there were nine causes for holes in the brain: 1. Small processes of sclerosed meninges, in cases of general paralysis, dipped into and excavated minute portions of cerebral tissue. 2. In the same disease the sclerosed neuroglia, by its contraction, might give rise to small cavities. 3. There might be multiple hydatids in the brain. These three conditions were very rare, the authors having no knowledge of the second, while the third was almost confined to animals suffering from staggers. Several references to continental authors were given, while the relation of the muslin appearance to the second of the above was pointed out. 4. The fourth cause was the dilatation of cerebral vessels giving rise to the "état criblé." It was particularly emphasized that this was, in the majority of cases, of no pathological significance. 5. Shrinking of the cerebral convolutions in some cases gave rise to holes in the subjacent cerebral substance; a very good example of this condition was exhibited. 6. Miliary aneurysms, as Charcot had pointed out, might give rise to holes in the brain-substance; some very marked specimens showing this were exhibited. 7. In the condition known in Germany as *die Porencephalie*, a large gap existed in the brain-substance; this might communicate either with the exterior or the interior of the brain, or both. 8. The Gruyère cheese condition. This, it was pointed out, was quite different from the *état criblé*, for it was due to a dilatation of the perivascular lymphatic space of Hiss. Of the causes of this dilatation nothing was known; probably they were local, so the dilatation was saccular. The authors showed an example of this condition in which the whole of the brain, except the lower part of the medulla, was riddled with cavities exactly like those found in cheese, and microscopic specimens exhibited

showed that these holes were produced by this perivascular dilatation. The shape and direction of the cavities also corresponded with those of the vessels. Very few examples of this condition had been carefully described; in England only one, by Leekhart Clarke, who referred it to the same cause. 9. The authors showed specimens from two remarkable cases in which the kidneys, lungs, liver, heart, and brain all contained holes; in the kidneys the cysts were due to the dilatation of either the tubules or Malpighian capsules; in the liver they were due to the vacuolation of the hepatic cells; in the lungs and brain it was impossible to come to any definite conclusion as to their origin, but in both these viscera the cavities contained a peculiar material, staining deeply with logwood; both the subjects were lunatics. Cases in which there were only a few holes, such as patches of softening hæmorrhage, were not considered to come within the scope of the paper.

SHOULD WOMEN RIDE LIKE MEN?—Such is the question which is being seriously discussed in the columns of a contemporary. Perhaps it would be as well to leave the determination of the question to those whom it principally concerns. We fancy they have no wish to change the custom. As a matter of fact, although it may not appear to be the case, the seat which a woman enjoys on a side-saddled horse is fully as secure, and not nearly as irksome, as that which a man has to maintain, unless he simply balances himself and does not grip the sides of his horse either with the knee or the side of the leg. It is curious to note the different ways in which the legs of men who pass much time in the saddle are affected. Riding with a straight leg and a long stirrup almost invariably produces what are popularly called knuckled-knees. Nearly all the mounted soldiers of the British army suffer from this deformity, as any one who will take the trouble to notice the men of the Life Guards and Blues walking may satisfy himself. On the other hand, riding with a short stirrup produces bowed-legs. Jockeys, grooms, and most hunting men who ride very frequently are more or less bow-legged. The long stirrup rider grips his horse with the knee, while the short stirrup rider grips him with the inner side of the leg below the knee. This difference of action explains the difference of result. No deformity necessarily follows the use of the side-saddle if the precaution be taken with growing girls to change sides on alternate days, riding on the left side one day and the right on the next. The purpose of this change is to counteract the tendency to lean over to the side opposite that on which the leg is swung.—*Lancet*.

A NEW BRITISH PHARMACOPEIA—A new edition of the British Pharmacopœia will be published before long. According to the "Lancet," the Pharmacopœia Committee have reported an arrangement to the Council by which, under their direction, Professors Redwood, Bentley, and Atfield will undertake the duty of preparing this edition. The remuneration to these gentlemen is to be £800. Their report is a document which will repay perusal. They recommend considerable changes in chemical nomenclature, in symbol notation, and in the method of representing the quantities of ingredients to be used in the preparation of medicines. They advise the addition of twenty-nine articles, and the omission of three.

SIR HENRY THOMPSON ON CIGARETTE SMOKING—Sir Henry Thompson writes to the "Lancet" as follows: "I think I might, if permitted, offer you a practical hint of some value in connection with cigarette smoking, which I think is not altogether appreciated by the author of your notes on the subject.

"First, the cigarette, without a mouthpiece, is really never smoked more than half way through in the East, where cigarettes are very cheap. It is well understood there, as it is by all practiced cigarette smokers, that every inhalation from a cigarette slightly deteriorates in quality from the first. A small deposit of the very offensive oil of tobacco is deposited in the finely cut leaf, which acts as a strainer, and intercepts the deposit as it passes. Very little of this arrives in the smoker's mouth if he stops when half is consumed. I have seen many Oriental smokers who consume no more than a third. Turkish ladies, for example, as I have had personal opportunities of observing at Constantinople, will smoke fifty or upward in a day, but, I need scarcely say, only in the manner I have described.

"Secondly, if a cigarette with a card mouthpiece is employed, the noxious matter may be intercepted by always introducing a light plug of cotton wool into the tube. If now the cigarette is nearly consumed, a considerable quantity of smoke and very offensive odor will be found in the cotton wool, from the evil of which the smoker is thus preserved.

"Thirdly, some years ago I designed a cigarette-holder or mouth-piece, which opened transversely in the middle, disclosing a small cavity, which is filled with cotton wool. It would surprise many people, perhaps, to find that the result of smoking six cigarettes only in this tube is that this plug is saturated with a brown fluid like treacle, of powerfully offensive odor, and disagreeable almost beyond belief. The wool then requires to be changed, and in this case the evil of smoking is very greatly diminished. Several of these are constructed by a well-known tobacconist close to your office in the Strand.

"Lastly, the maximum of pernicious influence which occurs through cigarette smoking is attained by the practice of inhaling the smoke largely direct into the lungs, where it comes into immediate contact with the circulation, and the toxic effect is so strongly pre-potent after three or four consecutive inhalations, and so felt by a sensitive person to the very tips of the fingers. I have no doubt that the effect would in most cases be notably recorded by the sphygmograph. Such smoking is, of course, or ought to be, exceptional. All the fragrance, with a little only of the toxic effect, is obtained by admission of the smoke into the mouth only, still more by passing it through the passages of the pharynx and nose; but it is the pulmonary condition referred to, often associated with cigarette smoking and finally with the pipe which constitutes the chief mischief of the cigarette. I may say, in passing, that that well-known Oriental method of smoking, practiced by means of the narghileh, in which the smoke, although drawn through water, passes invariably through the lungs, explains the powerful effects which sometimes unpleasantly surprise novices in its use.

"Smoked, then, simply, and with cotton wool interposed, I do not hesitate to regard the cigarette as the least potent, and therefore the least injurious, form of tobacco smoking. Without this precaution, it may be made, although not necessarily, the most ready means of conveying the active principle of tobacco, by means of smoke, into the system."

PEROXIDE OF HYDROGEN—Side by side with the increase in our knowledge of septic agencies in disease, says the "Lancet," there has grown up a long series of antiseptic substances, one some of which different observers have placed varying amounts of reliance. Among the most recent an antiseptic must be mentioned the peroxide of hydrogen, the use of which was first advocated, we believe, by Kingzett, in this country, and which is said to form the active principle of the "sanitas" preparations. In France, MM. Paul Bert and Regnard have paid special attention to the properties of this oxygenated water. Its use has been proposed and carried out by many surgeons in the treatment of unhealthy wounds; it seems to have been particularly valuable in bringing about a healthy action in atonic ulcers. Encouraging results have also been obtained from its employment in contagious diseases, such as some forms of ophthalmia, purulent cystitis, and the like. The peroxide of hydrogen is believed to act by destroying the activity of the micro-organisms of disease. The most recent communication on the use of the peroxide was made by MM. Paul Bert and Regnard before the Société de Biologie de Paris. Its employment was suggested in the treatment of deep-seated, irregular-shaped abscesses, in certain cysts of undoubted parasitic origin, and in many forms of diarrhoea which were known to be associated with an increase in the number of lowly organisms, and the presence of which probably had a considerable influence on the progress of the diarrhoea. In a similar fashion a tenuous antiseptic ought to be employed in the treatment of such cases, and the oxygenated water ought to be administered in the intervals of food, because it is said to be gradually absorbed by its presence. The inhalation of the medicinal vapours of ozone was suggested for cases of pulmonary phthisis, the contagiousness of which disease is regarded as beyond doubt. The most recent method of the inhalation is said to be the destruction of the living contagium. It is true, the authors say, that some microbes are provided with a protecting envelope, which

sets at defiance external agencies; but we yet require to know whether this is the case with the germs of phthisis. Further experiments must be made with a view to determine whether the bacillus of phthisis can be destroyed by peroxide of hydrogen. Some bacteria are certainly not damaged by it; in this group come the bacillus of charbon and of glanders. The evidence for the assertion concerning the bacillus of glanders rests on the following experiment made by the authors. Some diseased tissues from a case of glanders were treated with peroxide of hydrogen on the one hand and with simple water on the other. Inoculations performed on two mules led to the death of both animals, though one had been vaccinated from the virus which had been submitted to the action of the oxygenated water.

THE MEDICAL PROFESSION AND THE PLEA OF INSANITY.—After remarking that Mr. Justice Kay is of opinion that "the medical profession is only too ready to attribute acts which are out of the ordinary course, and especially acts of violence, to insanity," the "Lancet" says: "This is the impression which prevails among the judges generally. Recognizing the existence of this feeling, practitioners should undoubtedly exercise the greatest possible care in the expression of any opinion on the mental state of persons accused or convicted of crime. It would be a grievous hindrance to the cause of scientific truth and progress if ground were given for the strengthening of the injurious impression which prevails. Neither fear nor favor can be allowed to affect the judgment at which a medical man arrives after careful examination of his case; but the knowledge that his opinion is likely to be received with reluctance, or even an adverse bias, if it happened to be of a particular kind, should certainly be taken into consideration in forming a judgment, and ought to render him in a very special sense careful to eliminate all sources of error from the bases of his inference, and to see that it is so formed that it may be energetically and forcibly supported in the face of any question which may subsequently arise."

ANÆSTHETIZATION DURING SLEEP.—Apropos of Dr. J. H. Girdner's recent article in the "Medical Record," Dr. W. A. Mansfield, of Champaign, Ill., writes as follows to the "Weekly Medical Review": "After seeing his article I performed an experiment upon a healthy young man of twenty-five years, with the result of completely narcotizing him without his awakening or showing any sign of consciousness, only as I pinched him in the first stage of the process to see how far it had progressed. As a primary condition he did not know that I intended to try the experiment. He was in good health, and had performed a reasonably hard day's work. After he had become rather soundly asleep I administered chloroform by a handkerchief, holding at first about eight inches away from his face, and soon laying the handkerchief directly upon his face. There was no coughing or struggling, more than a slight movement of the arms and turning away of the head once or twice. I carried the narcosis so far that there was no wincing upon pinching or pulling the hairs, or upon touching the conjunctiva. The limbs, too, were completely relaxed. I hold that the above single experiment completely disproves the statement that chloroform narcosis can not be performed upon a sleeping man without an intervening state of consciousness. A single successful experiment like the above will at least prove the fact while five or five thousand experiments with negative results could show nothing more than a probability. Moreover, Dr. Girdner's experiments were performed upon subjects who were in an abnormal condition through disease. That narcotism from chloroform without consciousness may be accomplished is a fact, but more experiments are needed to show whether it may be accomplished upon many individuals."

IS A TENDENCY TO DEATH DURING PARTURITION HEREDITARY?—Dr. W. Henry Day writes to the "Lancet" as follows: "I was recently consulted by a young married lady, aged twenty-two, for troubles connected with the early stage of her first pregnancy. She is a fragile little body, of English parentage, but born in India. Finding on inquiry she was in the habit of staying in-doors for days together codling and reading, I tried to impress upon her the necessity of taking plenty of out-door exercise, so as to raise her physiological tone to its highest pitch, as a medical man would view with considerable anxiety the accouchement of a woman who indulged in such indolent habits,

when she volunteered the following extraordinary statement: 'My mother, grandmother, and great-grandmother all died in their first confinement.' Her mother married at seventeen and died at nineteen, three days after instrumental delivery, in India. She does not know any of the particulars of the other deaths, only the fact that each gave birth to a daughter and then died. Out of over fifteen hundred cases of midwifery I have attended, I am thankful to say I have only had two maternal deaths, and in one of them hereditary tendency seemed to be an influence at work. It is over twenty years ago now. I attended the woman in her third and fourth labors. After the last she died of puerperal mania. The husband, when he called for the certificate of death, said: 'It is a remarkable thing; both my wives died in their fourth labor, and they were sisters.'"

THE "MEDICAL CHRONICLE" ON THE CODE CONTROVERSY.—The June number of the Baltimore "Medical Chronicle" says: "The fight over the code of ethics waxes hotter and hotter as the time of meeting of the American Medical Association approaches. At every State society meeting during the spring, resolutions of loyalty to the code have been passed, and the recalcitrant members of the New York State Society unanimously censured in presidential addresses. It seems to us that an unnecessary amount of denunciation of the so-called rebellion in New York has been indulged in by supporters of the code, who have, with singular unanimity, left out of view the true merits of the question. We can hardly believe that the thinking members of the profession outside of New York regard the code as so perfect an instrument that no amendment of it is possible. There is, however, very little probability of action looking to any modification of the code in the present state of professional opinion. We can only regret this, as it tends daily to widen the breach between the profession in New York and the rest of the country. The fight as it is conducted now is hardly a dignified one. There is too much suggestion of the political ward meeting in the way in which the discussion is carried on, and resolutions passed. The spirit which causes the severance of old friendships, the bitterness of partisan strife, the accusations of dishonesty in intent and practice, the threats of 'boycotting'—all are foreign to the true spirit of the profession, and should be banished at once. Can not the old wiser heads in the profession, those to whom we have all listened and heeded in the past, counsel calmness in this juncture and restore harmony to the profession throughout the country?"

THE "EPHEMERIS" ON THE RECENT ACTION OF THE ACADEMY OF MEDICINE.—Referring to the late action of the Academy in instructing its Committee on Admissions not to recommend any candidate who could not conscientiously pledge himself to support the Academy's code of ethics, the "Ephemeris of Materia Medica," a staunch supporter of the Academy's action, says: "There is nothing in the action to indicate any opposition to a member's pledging himself honestly to the existing laws, and then after admission as honestly changing his mind and then working against his signature which carried former convictions now changed."

THE ILLINOIS STATE BOARD OF HEALTH.—We learn that the board is revising its "Directory of the Institutions Granting Medical Diplomas or Licenses in the United States and Canada." Copies of the last issue are being sent to the medical colleges asking for corrections and additions, at the same time reminding the colleges that the schedule of "Minimum Requirements" as to the good standing of schools in that State is now in force.

THE ASSOCIATION FRANÇAISE POUR L'AVANCEMENT DES SCIENCES will hold its next meeting at Rouen, beginning August 16th.

SOCIETY MEETINGS FOR THE COMING WEEK.—Tuesday, June 26th: New York Academy of Medicine (Council); New York Dermatological Society (private); Medical Society of the County of Lewis, N. Y. (annual); Medical Society of the County of Washington, N. Y. (annual); Jersey City Pathological Society. Wednesday, June 27th: New York Pathological Society; New York Medico-Legal Society, Auburn (N. Y.); City Medical Association. Thursday, June 28th: New York Academy of Medicine (Section in Obstetrics).

Lectures and Addresses.

LECTURES ON HUMAN AUTOMATISM.

DELIVERED AT THE LOWELL INSTITUTE, BOSTON.

By WILLIAM B. CARPENTER, M.D., LL.D., F.R.S., Etc.

LECTURE V.

(Continued from page 675.)

I shall first give you one example that will show you the way in which the mind may act immediately upon a resultant previously arrived at, and without any recollection either of the idea itself or of the process by which it had been worked out. A valued friend of mine, in his early life, was an *attaché* to the British Embassy at Vienna, and was accustomed very frequently to go to the opera, where the *attachés* of the different embassies had what is called an "omnibus box" close to the stage, in which they used to meet and gossip about politics, or society, or the opera, or anything else that might be of interest to them. There had been a very sad story in the English papers in regard to a *danseuse* at one of the London theatres having been burned to death by the catching fire of her clothes from the stage-lights; and, this being discussed among those gentlemen, my friend said: "Well, now, supposing that were to happen to a *danseuse* on the stage below, I should get over *here*, and then I should put the next foot *there*, and the next foot *there*, and the next foot *there*, and I should be down on the stage directly; and I would throw my overcoat round her and put the fire out." About a fortnight or three weeks afterward my friend was there again, but with a mind entirely pre-occupied by other matters of absorbing interest to him. He was sitting, as he has told me, with his head buried beneath his hands, thinking of these matters, when a cry was raised of fire on the stage; he got down directly on the stage and put out the fire by his coat in what one might almost call the twinkling of an eye. He assured me that he had not, at the time, the slightest recollection of the former occurrence, and had acted instantaneously, without stopping to think, when suddenly aroused from his reverie by the cry. But he afterward learned from his friend that he had put his feet successively down on each of the points he had previously fixed upon.

Now, I can not but think that, although my friend had at the time no recollection whatever of having previously worked out the steps of the descent from his box to the stage, his course was really determined by the unconscious impress left by the former discussion. And I believe that our automatism, working unconsciously along the tracks laid down by a previous course of training, will often resolve difficulties which we vainly endeavor to surmount by the volitional direction of our minds to the subject; so that, as in the case of a wanted memory that will not come at call, it is often better to try the effect of leaving the puzzle to unravel itself. I have collected a great many instances of this kind in which, when a difficulty had been experi-

enced—the subject having been pursued as far as the then ability of the seeker (whether in mechanical invention, in a knotty question of logic, or other abstract science, in poetry, in music, or in working out a story) could carry it—and the matter had been laid aside for a week, a fortnight, or three weeks, the solution has presented itself quite suddenly, without any intermediate conscious thought upon the subject.

The invention of the little prism of the binocular microscope, which was made by Mr. Wenham, was the result of a process of this kind. He had thought that it was possible to construct a stereoscopic binocular on some simpler plan than the combination of three prisms which was then in use; and that the required division and recombination of the images might possibly be effected by a single prism. But he could not hit upon the form of prism that should produce the result; and, after much thought, he put the matter altogether aside for a time. His attention (he has assured me) was turned entirely to an engineering business which he was then commencing; but, coming home tired one evening, he took up "a stupid novel" by way of recreation, and while he was reading it the form of the prism which would do this work flashed into his mind. He then took his mathematical instruments and worked out on paper the angles of the prism which should give the necessary reflections; and the next morning he made his prism, and found it perfectly successful.

I believe that many of our best judgments are formed by the same automatic and unconscious process; and of this I will give you a curious example which fell within my own knowledge a few years ago. A gentleman of very considerable intelligence, with whom I had been conversing on this subject, told me that not long previously he had been requested by a lady, with whom he had for many years been in habits of intimacy, to act as her executor; to which request he acceded. On her death, which occurred soon afterward, he found himself in a position of very peculiar difficulty. She had a considerable property to leave, and no near relations, but a number of distant relatives who considered themselves to have claims upon her; and she did not herself determine how her property should be distributed among them, probably evading the question as one of difficulty and perplexity, with which, feeling her end approaching, she did not wish to be troubled, and leaving it entirely to my friend's judgment to make such a disposition of it as he might deem most fitting. He pondered a good deal over this question, being very desirous to do what was right and just all round, feeling strongly his responsibility, and knowing very well that he should disoblige some, probably all, of these expectant heirs. At last he framed a scheme which he thought was as good as he could probably make it; but still he was not satisfied with it, and very wisely put it aside for a time, with the purpose of taking it up again for reconsideration when his mind should have been refreshed by a change of subject. He gave his attention continuously to his own affairs for some two or three weeks, purposely abstaining from thinking of this matter at all; and one morning, after a sound night's sleep,

he awoke with a new plan distinctly present to his mind, of which he at once felt "this is the right thing to do." It approved itself to his judgment as so complete and satisfactory that he at once proceeded to act upon it, and has never since had reason to question the soundness of the arrangement.

I believe that in this case my friend's mind, previously trained in business habits, strongly desiring to do the right thing, and having had before it all the considerations which could lead to a correct judgment, had set his brain to work out the conclusion—just as Sir William Thomson's tide-machine calculates the tide-table for any place in accordance with the data to which it has been adjusted. At any rate, the action was both automatic and unconscious, and it seems to me a misuse of terms to call it mental.

I have had in my own experience several examples which I could narrate of the same kind, showing the advantage of what a friend of mine calls the "hanging-up" of such difficulty, and of abstaining as much as possible from the conscious direction of the mind to it—provided that we have already kept the matter sufficiently long before us, and viewed it in all its aspects. And I would recommend to you this "hanging-up," when there is time to put it in practice, as our best method of dealing with questions not only of prudential conduct, but also of what we *ought* to do in those difficult cases in which *what is* the right course is not clear to our moral sense. The trust which we may safely place in the working of this automatic process will depend upon what we may call the construction of the machine and the correctness of its adjustments. The habitual direction of our mind must have been good and judicious, and we must have aimed to look at the subject all round, giving due consideration to whatever can be said on every side. If, on the other hand, we determinately shut our minds to one set of considerations, and look only at another, our automatic judgment, like the turning of a balance, will, of course, be one-sided and worthless. I would apply the same principle to the formation of our beliefs. It has been often said that we are not responsible for our beliefs, while it is also a common saying that we can easily believe what we wish to believe. Now, I think there is truth in each of these two statements. We are not responsible for our beliefs if we really have exercised ourselves in giving due weight to all the evidentiary data by which these beliefs should be decided. Our belief in any proposition is, as it seems to me, the fitting of that proposition into our previous fabric of thought; it approves itself to our mind, we accept it as a part of our consciousness; we can not help our belief in it. But what had been the previous process? If we really desire to arrive at the truth, we look at the subject in every aspect, and give to every consideration that bears on it that weight which we may honestly believe it to deserve. We try to regard it not merely from our own point of view—which has been fixed by our own previous habits of thought—but as much as we possibly can from other people's point of view. And here, as it seems to me, is the great benefit of *discussion*, which not only supplies us with evidentiary materials which we might ourselves have overlooked, but enables us to see

how differently those evidences are appreciated by others, according to *their* previous habits of thought. It has happened to me quite recently to have found myself unable to enter into the mind of a scientific opponent until I went personally to discuss the matter with him, and to be shown by him the facts on which his conclusions were based; and I then found that, from his point of view, there was a great deal more to be said for these conclusions than I had previously been able to apprehend.

Now, when we have thus taken all the pains we can to inform ourselves thoroughly, and have freed ourselves as far as possible from any kind of self-interested bias (in which I include the pride which resists the acknowledgment of a previous error), our decision must, like the turning of a balance, be independent of our will; and thus we *are not* responsible for it. But, on the other hand, if we determinately shut our eyes to considerations which ought to have great weight with us, allowing ourselves to dwell only on those which best fit in with our previous fabric of thought, without allowing ourselves to question the soundness of the foundations of that fabric, we *are* responsible for our erroneous conclusion. You all know the story of the two knights and the shield which was golden on one side and silver on the other; one of them saw the gold side and the other the silver side, and they fought with each other until at last, having changed their relative positions, they discovered that their difference depended on their having first seen the shield from opposite sides. Now, this is the case with most of us, more or less. There are few of our beliefs in which our feelings do not come in one way or another to be interested, and thus to exert an influence on our judgment. We can scarcely help, if we have once taken a side, desiring to find that side true. The first element, then, in the formation of a sound judgment is as much as possible to dismiss all such desire. And how are we to dismiss it? By fixing our attention upon the question itself, and determinately directing it to the facts which shall show where the truth lies, rather than to our own particular view of those facts.

There are many persons who have a wonderful confidence in themselves, and can not conceive that any other view of a case can be the right one than that which they have been accustomed to entertain. Lord Macaulay was a type of this character. He would spare no pains, in writing his "History," to get at all the facts of a case—or what he deemed to be the facts. He looked more completely round it in the first instance than most persons do; though he looked, perhaps, rather too exclusively through Whig spectacles, he honestly meant to get all the information he could, and to decide upon the evidence. But, having once made up his mind upon any point, it was impossible to shake his conviction. The quantity of additional evidence that was produced to rebut two or three of his conclusions would have influenced, I believe, most other men; but Lord Macaulay believed in himself so implicitly that this evidence could not make the impression upon him that it did upon every one else. Now, I think we may take it as a fact that if we find our most assured convictions to be in discordance with those of educated and cultured

men, whom we regard as influenced equally with ourselves by an honest desire to arrive at the truth, our conclusions, though not necessarily wrong, lack the certainty that we are disposed to regard them as possessing. There must be some other mode of looking at the matter, another standpoint in which we have not placed ourselves; and we ought to open our minds to the suspicion that we may possibly, when we have taken *everything* into account, find ourselves in the wrong. Now, these are practical considerations, which I think you will see arise directly out of the consideration of this subject of automatism. The inclination of the balance is, I believe, purely automatic; but the bringing together the evidence, and the attaching more or less value to this or that evidential fact, is the part of the process over which we have a very considerable amount of volitional control. We can direct our attention to the evidential facts on our own side, to the exclusion of those facts on the other side, just as a judge who has a strong political bias (we have had plenty of cases of that kind within my own recollection, but I hope that such a bias is a thing of the past, both with ourselves and with you) has given much greater weight to the evidence on the side which he favored than to that on the other side, and would strain a legal point to admit evidence that was a little questionable on the one side, while taking every possible means of keeping out evidence on the other side. This is just what the one-sided inquirer is very apt to do. He *wishes* his belief to take a certain direction; and (unconsciously to himself, it may be) he lets his mind move in that direction, without attending to any of the signs that would indicate to disinterested bystanders that he is going wrong. And he thus makes himself responsible for any error in the conclusion at which his judgment may arrive.

The "motive powers" which give the impetus to our mental activity were to have constituted the special subject of this evening's lecture, but I have thought, on the whole, better to dwell upon the automatism of our intellectual nature, because the higher forms of these motive powers will very fitly be combined with the subject which will form the topic of the concluding lecture of this course—the automatism of our *moral* nature.

There is no necessity to dwell on the fact that the lower forms of the motive powers have their origin in our corporeal requirements, for daily experience brings it before our consciousness. The need of food and the need of oxygen constitute, from the moment of our entrance into the world, the most potent and the most constant of our springs of action; and I have shown you how those needs act as "motive powers" to our physical automatism. The need for oxygen ordinarily finds its satisfaction in the inhalation of the atmospheric air by which we are everywhere surrounded; but when the supply of that air is insufficient, the craving for it becomes more intense than the severest pangs of hunger or thirst, and may excite the strongest efforts, the most violent struggles for its relief, overcoming all sense of the equal rights of others, as those will remember who have read the fearful, never-to-be-forgotten narrative of the sufferings of the prisoners crowded together in "The Black Hole of Calcutta." The craving for food

and water requires only occasional satisfaction; and, when the supply is within reach, the physical automatism alone suffices for its introduction into the stomach. The sucking, like the breathing, of the infant is a purely "reflex" action, which may be, probably is, performed even without consciousness; but the senses soon come to act as guides to the source of food; and it becomes clear that the want of it is *felt* as a desire. During early childhood this desire is obviously more potent than any other, what the phrenologists call "alimentativeness" and "grustativeness" constituting the principal springs of action; but, as the food is provided for the child, and not *by* it, the desire does not directly bring into play the higher capacities of its nature. In adult life, on the other hand, the making provision for the material wants, not only of himself, but of those dependent upon him, becomes the primal object of every man who is not above the need of doing so; it shapes his plan of life, and keeps him to the steady pursuance of it by the exercise of whatever ability he may possess. And this it does without being constantly present to his mind; for, while engaged in his daily round of duties, he thinks rather of these than of the remote purpose for which he undertook them. Yet, however automatically these duties may come by habit to be performed, their course was first volitionally shaped out at the prompting of an imperious motive; and this motive asserts itself forcibly whenever the attention is called to it by any impending failure in the needful supplies. We see the exemplification of this in that primal grade of human society—which constitutes the entire community in the least civilized nations, but only the lowest stratum in those which have learned the value of the "division of labor"—that in which each family depends on the supply of food provided by its own exertions in hunting and fishing, the cultivation of the soil, or the rearing of domestic animals. What can be in stronger contrast than the sluggish life of the Orinoco Indian—for whom one day's labor (in the planting of a banana-grove) is said by Humboldt to be sufficient to provide food for the whole year, and who divides his time between sleeping and smoking—and the hardy activity of the Swiss mountaineer, who toils throughout the summer and autumn in the cultivation of his small patch of grain or potatoes for the needs of his family, and scales heights that most men would deem inaccessible to collect their scanty herbage as winter's food for his beasts, using the long hours of his enforced confinement in some kind of skillful handiwork which may enable him to procure additional comforts for his home, or educational advantages for his children? And so, in the higher grades of society, those who are born "with a silver spoon in their mouths" too often fall into habits of mere dilettanteism, while those who enter upon their career with good educational preparation for it, but without any other basis of subsistence than what they can themselves earn, are (as a large experience shows) those most likely to succeed. I need not call to your minds cases so familiar to you as those of your own Presidents Lincoln and Garfield, but would rather draw my illustration from the fact well known in my reputedly aristocratic country—that none of the men who have risen to the highest eminence in the legal profes-

sion, and have thereby gained seats in our House of Lords, have begun life upon nothing, while those who go to the bar with an income that places them above the need of exertion are regarded as almost sure *not* to "get on." The autobiography of the late Lord Campbell and the biographical notices that have made us acquainted with the early years of the late Lord Justice Lush are most instructive when regarded in this aspect, showing what steady determination may do without any brilliant ability when nerved in the first instance by the "stimulus of necessity." And so it is with most of us. In proportion as our path of life is smooth and even, we tend to fall into an automatic routine; but obstacles arise which require some extraordinary exertion to surmount them; and then only do we become conscious of our real strength—that which lies in *vigorous self-determination*.

"The wise and active conquer difficulties
By daring to attempt them. Sloth and folly
Shiver and shrink at the sight of toil and danger,
And make the impossibilities they fear."

Original Communications.

THE DEVELOPMENT OF CANCER FROM NON-MALIGNANT DISEASES.*

By DANIEL LEWIS, M. D.,

ASSISTANT PHYSICIAN TO THE NEW YORK SKIN AND CANCER HOSPITAL.

THE frequency with which patients attribute cancer to some non-malignant disease or condition as the exciting, if not the primary cause, is familiar to every observer of such cases.

Medical literature abounds in isolated instances of such development, and my purpose is to so group them as to form reliable premises for deductions concerning the origin of cancer.

Warty growths should be named near the head of the list, on account of the frequency with which they have been observed to become cancerous. In a paper published in the "American Practitioner" for December, 1874, I gave a brief report of a case (No. I) occurring in a man, fifty-five years of age, who had a small wart on the right side of the nose, about three quarters of an inch from the angle of the eye, which had existed many years, without showing any sign of malignancy. Two years before its removal it became slightly ulcerated, without any known cause, and from that time forward it increased gradually in size until at the end of the two years it was an unmistakable epithelioma. The cervical glands were considerably enlarged. It was removed by Marsden's arsenical mucilage, and healed completely; but the patient died two years later of cancer of the left lung.

Dr. Thin relates a case, in the "Transactions of the

* Read before the Medical Society of the State of New York, February 7, 1883.

London Pathological Society," vol. xxx, p. 374, of rodent ulcer, which began, four years before its final removal by operation, as a little wart by the side of the nose, the lip of that side being at the same time swollen, on account of inflammation of the eye-tooth.

It increased in size very slowly, and three years after its commencement caustic was applied, which seemed to improve it at first; but it soon began to increase rapidly, and when removed, twelve months later, it was an ulcer one half-inch by an inch.

Microscopical examination of sections through the border and surface of the ulcer exhibited the usual cell arrangement of rodent ulcer.

In both of these cases there is no history of heredity, and in my own case the history is authentic for at least two generations.

The same process is noticed in the development of cancer from warts which usually marks epithelioma of the lip—viz., the formation and removal of a scab upon its surface, and the gradual development of the sore.

Sebaceous tumors often result in cancer after they have existed for long periods without showing any malignant tendency. Sometimes, when middle life is reached and the tendency to degenerative changes is at its maximum, these growths will begin to show signs of activity; some tenderness and pain, less mobility, and a thickening of the walls near the base of the tumor, are often among the first changes noted. Ulceration follows later, and the course of the disease thenceforth does not differ from that of cancer from other causes.

Injuries play an important part in other cases; and the following case, occurring in the practice of Dr. W. W. Crandall, of Andover, will furnish an excellent illustration:

A man, aged fifty-five, with a wen on the vertex, one inch and a half in its longest diameter, which had existed for a score of years or more, accidentally struck it against a sharp piece of wood, which, if I remember rightly, caused slight bleeding. Inflammation of the tumor followed, then ulceration and sloughing, which was followed, after a few weeks, by cancerous disease of the entire border and even base of the ulcer. It was finally removed by Marsden's method, and the history was published in the paper above mentioned. There was no family history of cancer.

Mr. C. Aston Key has reported a case of sebaceous tumor of the scalp ("Trans. London Path. Soc.," vol. i, p. 345) which he removed from the scalp of a lady sixty-nine years of age. The top of the tumor had sloughed, the margin of the opening assumed a cancerous character, and, after the whole tumor was removed, a quantity of glairy fluid was found at its lower portion, having all the physical appearance of colloid. Family history not mentioned.

Numerous instances are recorded in which the ordinary mole became the seat of cancerous disease.

Mr. H. Thompson reported the following case at a meeting of the London Pathological Society, November 6, 1860:

A lady, aged sixty, was subject from birth to a small black mole on the outer side of the left arm.

It became irritated in hot weather for two summers, the second time remaining red and swollen, and a melanoid

cancer of the size of a large nut resulted, which was attended with a large glandular tumor in the axilla of the same side.

It seems that the melanoid variety of cancer chooses the neighborhood of a congenital mole, or wart, for its development, as in the instance just related.

Mr. Pemberton, of the Birmingham General Hospital, in his work on cancer, emphasizes this point, and one of his cases is so characteristic that I will give it as he relates it:

Mrs. M. H., aged forty-five, had several congenital moles on different parts of the body, one of which was near the middle of the forearm.

Ulceration began around its edge first, and spread therefrom, leaving the mole untouched. At the end of four years, an irregular ulcer, two inches in its longest diameter, was produced, with borders elevated, dark-colored, and indurated.

The entire portion was removed by operation down to the muscles beneath, and, four years later, she remained well. There were no enlarged glands, and no history of cancer in the family.

Other varieties of cancer than the melanoid often develop in moles, however, and the same author (Pemberton) relates several cases where an irritation or slight injury of a congenital mole was followed by the encephaloid variety.

Syphilis is often the direct cause of cancer, especially when the disease appears as a chronic ulcer of the tongue. The extreme difficulty of curing these syphilitic sores by the ordinary treatment is doubtless familiar to every practitioner.

I have recently seen a syphilitic patient, who had been under treatment in hospital for several months with ulceration of the tongue, develop an affection of the parotid and sublingual glands of the same side, which was undoubtedly malignant.

Walsh ("The Nature and Treatment of Cancer," p. 155) does not admit that syphilis is a cause of cancer, and brings forward arguments against it, the chief one being that it is a rare disease among prostitutes, in whom syphilis is presumably quite common. This argument loses its force when the age of that class is considered, the average of which is much below that at which cancer most frequently occurs.

Scirrhus of the penis has been observed to spring from a syphilitic sore, and even Walsh says (p. 408): "Venereal ulcers may become complicated by carcinomatous deposition and fungate in the same manner as primary cancer." The same authority also declares that venereal warts may terminate in cancer.

It may not be out of place to mention here that cancer of the penis has been so frequently observed associated with congenital phimosis that many writers have placed it among the causes of the disease, and the retention of the natural secretions is believed to be the exciting cause. Ten patients out of twelve, treated for cancer of the penis by Hey, had either congenital or acquired phimosis.

The development of cancer of the breast, when a chronic eczema of the nipple had existed for a long time, has naturally led to the inference that they stood in the relation of cause and effect.

Mr. Henry Morris, of the Middlesex Hospital, reported two cases in the "Med.-Chirurg. Transactions" (vol. lxiii, p. 37), in one of which cases the eruption existed four years, and in the other six, before cancer was suspected. Both patients died of secondary cancer.

Mr. Thomas W. Nunn, in his recent admirable work on "Cancer of the Breast," refers to Mr. Morris's cases in connection with one observed by himself, and also furnishes the conclusions arrived at by Mr. H. T. Butlin, in a paper on the same subject.

I take the liberty of copying Mr. Butlin's propositions as Mr. Nunn gives them:

1. That a certain relation existed between the eczema of the nipple and the areola and the carcinoma of the breast.
2. That one of the first effects of the eczema was to produce proliferation of the mucous layer of the epidermis of the parts affected.
3. That in time the epithelium lining the galactophorous ducts became affected in like manner.
4. That the disease, traveling along the large ducts, reached the smaller ducts and acini, which became dilated and filled with proliferating epithelium, which was at length, so to speak, discharged into the surrounding tissues.
5. That the carcinoma thus formed was therefore essentially a disease of epithelium.

Whether we accept this theory of production, or the opposing one of Dr. Thin—that, instead of a cell proliferation, the growth is the result of a special development of colorless blood corpuscles—the fact that cancer of the breast does result from eczema of the nipple and areola seems to be pretty well established.

The development of cancer in cicatrices of various kinds, especially burns, is too well recognized to need any comment.

Simple ulcers occasionally become malignant, and two very interesting cases of that kind are at present under treatment at the New York Skin and Cancer Hospital, in the service of Dr. Bulkley.

The first is that of a woman, aged fifty-five, who fell down a flight of stairs six years ago, receiving several cuts about the face by corners of zinc covering the steps. All healed except one on the right ala nasi, which continued to discharge a little watery fluid, and occasionally form a scab over it, until within the past year and a half, when it began to increase in size quite rapidly, and now is nearly two square inches in extent, and an unmistakable epithelioma. A second one has recently developed just below the left eye, and entirely distinct from the first ulcer. The patient is positive in her statement that no cancer has ever occurred in her family.

The second case is in a man, fifty-seven years of age, who received an abrasion of the skin on the left leg thirty years ago, which healed in a few weeks. Ever since that time, however, he has not had any healing of the abrasion, the injury, and scratching it has abraded the skin, and quite a large ulcer has grown from the center. It has not been healed for about six years; and during an attack of acute rheumatism, two years since, it began to increase in size, and, notwithstanding all the remedies applicable to such

cases have been employed for its cure, it has steadily advanced.

It is now a deep, irregular ulcer, extending from the ankle nine inches up the leg, its lateral diameter being about seven inches.

The surface is covered with irregular nodules and furrows, color dark red, and secreting a considerable watery fluid. The edges are elevated and indurated for nearly an inch from the border, and, when compressed firmly, exude a little fluid resembling pus. The entire ulcer is the seat of an almost constant burning pain, described by the patient like the sensation of having boiling water poured over it.

The man has been a coachman for thirty years, and was never sick. Even now his general appearance indicates good health. There is a bare possibility of heredity, as one brother died from some "sore" a few years ago.

An authentic case of cancer developed from an innocent ulcer is reported by Mr. Jonathan Hutchinson in the "Transactions of the London Pathological Society" (vol. viii, p. 404).

The patient was a woman, aged sixty, who had suffered from onychia of the right great toe for about eight months. It was said to have been caused by a tight shoe. When the remnants of dead nail were removed, the matrix and adjacent parts were in an inflamed and very irritable state, and resisted all efforts to heal them. The base of the ulcer became gradually thicker and more swollen, and, syphilis being suspected, iodide of potassium was administered, but without benefit.

Induration increased and pain became more severe, and of a darting, pricking character.

Enlarged glands were then discovered about the middle of the thigh, just over the large vessels where Mr. Hutchinson has several times observed the first glandular enlargement in melanosis of the foot. The glands of the groin were not affected. The toe was removed, and found to be the seat of melanotic and medullary cancer.

At that time the woman had not materially lost flesh, and was in good health, although the trouble had existed two years. Eight months later she returned with a bleeding mass of cancer in the groin, and also recurrent disease in the stump of the toe. In this case also there was no history of hereditary cancer.

Numerous cases similar to those here presented are recorded, but enough have been cited, I believe, to establish beyond question that cancer is not always the outgrowth of malignancy. In other words, in the cases here recorded there was a pre-cancerous stage, when the patient could have been cured by removing a simple sebaceous tumor or a wart—by a judicious management of an eczema of the nipple, or a lacerated wound of the face.

The importance of these practical considerations is apparent, but the chief interest of these cases, to my mind, lies in the evidence they furnish that the doctrine advanced by Mr. Hutchinson of a pre-cancerous stage in all cancer is correct.

In a paper on the "Origin of Tumors," which he presented at the last meeting of the British Medical Association, he traces similarities between inflammation and cancer,

and finally asserts that the former, by inducing a local senility of the part, may be classed among the predisposing causes of malignant disease.

The cases that I have here collected will show that the disease was invariably preceded by a local irritation, in some instances lasting many years; that some exciting cause produced an acute inflammation, and cancer was the result.

While the pre-cancerous stage is often so well marked as to be undeniable, it seems fair to assume that it may exist in every case, but, when the disease is very active, is sometimes submerged, as it were, before it is clearly recognized.

One other point deserves mention here, which is the fact that there is not a clear history of inheritance among all these cases. You will find this apparent in most of the statistics which have hitherto been published. The records of the London Cancer Hospital, as shown me through the courtesy of Dr. Marsden, are overwhelmingly against the so-called constitutional origin of cancer. Although Mr. Paget claims that the statements of patients regarding this point are not to be depended upon on this side of the argument, it is very difficult to understand why he so readily accepts the same kind of evidence when a patient declares that some near or remote relation did have a cancer.

The following propositions, based upon the clinical history of cancer, seem to be well sustained:

1. Many diseases of a non-malignant character are not only predisposing but exciting causes of cancer.
2. Such degeneration often occurs in patients who have no hereditary predisposition to cancer, and in those who are so predisposed the danger is imminent.
3. The recognition of the pre-cancerous stage of the disease is of the highest importance in its successful treatment.
4. While it is true that heredity is well attested in many cases, its importance has been greatly overestimated by all the older authorities and many writers of the present day.

147 EAST FORTY-FIFTH STREET, NEW YORK.

THE CLIMATIC TREATMENT OF PULMONARY CONSUMPTION; REPRESENTING THE OPINIONS OF THE PROFESSION IN REFERENCE TO CLIMATOLOGY AND CONSUMPTION.

By J. HILGARD TYNDALE, M. D.,
NEW YORK.

(Continued from page 682.)

"After this much premising, I turn to the questions.

"'1. ELEVATION.'"

"Question. 'Do you believe elevation to be a necessary factor?'

"Answer. Yes, for all those who can bear it without too marked dyspnea, and without irritability to the heart, nervous system, bronchial mucous membrane, etc. It is especially favorable for 'superficial inflammatory processes of the bronchi' (or peripheral portions of the lung), with lowered general condition, ditto 'infiltrations'; less so if com-

plicated with 'irritable heart, naso-pharyngeal, laryngeal, and bronchial mucous membranes'; and less so still according to complication with *excavation*; but more bearable if 'free down to the clavicles,'* i. e., free from pharyngitis, laryngitis, etc. The general rules I had previously given were such as these: 'The addition of rarefied air to the climatic prescription for a consumptive is *always* advisable when the same is not contraindicated for a definite cause.'

"The more an invalid is deprived of his normal breathing capacity by disease, and the more he feels obliged to remain in confined apartments, by so much are extreme elevations unsuitable for him.

"Elevation above the sea-level—location being favorable—increases such desirable attributes as stimulation, dryness, coolness, and diathermacy of the air; but, the more we increase it as a remedy for disease, the more we must qualify its use; or, the severer the disease, the less extreme should be the elevation. ('Transactions of the American Medical Association for 1879,' page 175).

"The reduced pressure of the air-column, such as exists at considerable elevations' (say four to eight thousand feet elevation at this latitude), has 'decided therapeutical effects upon the organism, independent of the purity or aseptic qualities of the atmosphere.' Of course, the unlimited amount of fresh air, and its greater and greater freedom from germs as elevation is increased, are very potent factors; the latter, I think, probably more so than the former. Yet outside of this, and accepting as conclusive Professor Tyndall's experiments as to the increasing freedom from atmospheric germs at increasing elevations, I believe there is a mechanical influence of the attenuated atmosphere which will account for no small part of the benefit consumptives receive in Colorado and such elevated sections. Especially is this so for those classes we might place under the heads of peripheral inflammatory processes and infiltrations in the lung parenchyma, and asthmatic spasms and hyperemias in the bronchial tract. The evidences as to the size of the chest, even in childhood, of the inhabitants of great elevations, and the increase in the circumference of the chest of those of my patients who improved in Colorado, bear strongly on this question of lessened atmospheric pressure.†

"To what particular region or health-station are you in the habit of directing your patients suffering from pulmonary consumption?"

"Answer. To no particular one. I dislike boarding-houses,

* I do not believe that the fact of there being complications or inflammatory disease of the mucous membrane "*above the clavicles*" should necessarily prevent a patient from resorting to high altitude climates. It is mainly the condition *below the clavicles* that should settle the question of climate. At the same time, I recognize that the suspicion of laryngeal phthisis, complicating serious disease in the lungs, is ominous of a fatal result, whatever climate is resorted to. Yet quite a number of my cases, who are doing as well as could be wished in Colorado, have been those who had suffered long courses of treatment by throat specialists before coming West, and before there was any definite knowledge of trouble *below the clavicle*.

† In the chapter on Altitude (pages 81 to 94, "Rocky Mountain Health-Resorts"), I have endeavored more fully to give my idea of how the proportionately increased outward pressure of the air when the lungs tends to prevent or dissipate infiltrations, hyperemias, etc.

etc., where consumptives congregate, passively abetting the depressing influence of their disease by their indoor life, by daily comparing symptoms, and by doing little to better themselves.

"My patients have done the best who have been able to enjoy life on a rancho, finding something to do with some genial farmer people, or living in the dry cañons among the foot-hills west of Denver. With good living insured—which is not always the case, I am sorry to say—these are the best kinds of life to lead. Among the foot-hills the facility for carrying out the 'climbing treatment' is, I think, of great advantage to many. Especially is this so for chronic interstitial pneumonias and hepatizations without softening, superficial inflammatory processes, in those with chests of deficient capacity, etc.

"In the vicinity of Fort Collins, or of Boulder, out on the plains east of Denver, both north and south of the divide, and in northern New Mexico (north of the 'Staked Plains,' or in the vicinities of Ojo Caliente, or Pagosa Springs), I have had patients do excellently well. The precise locality is not of so much account in eastern Colorado as the desirable elevation and exposure, together with the other considerations I have mentioned.

"Question. 'Do you differentiate as to summer and winter?'

"Answer. Yes. Especially for new patients, and those in whom arrest is not known to be established. As to the effect of elevation, there is a difference between summer and winter, which is equivalent to two thousand to three thousand feet. This, for summer, may be added to the suitable elevation in winter. Many of my patients do well in Estes Park, and the other mountain parks, in summer, for whom those locations would be out of the question in winter. Some of these spend the winter in Denver, and are satisfied that, better than elsewhere, they improve through the social attractions and good living to be there obtained. Others winter at Colorado Springs and Las Vegas; but there are a few on account of whom I have wished we were able more easily to send invalids to a lower and more sedative climate in winter than the conformation and extent of this Rocky Mountain region permits of doing. For those who do well, and can live here, the differentiation as to seasons is in the main impracticable; because such persons ought to settle down to do something, to be a part of some community, and have a calling to occupy their minds. It is often a difficult problem to solve, what to advise patients who have nothing themselves to do but to 'kill time,' or who are compelled to support themselves by their own limited exertions.

"Question. 'What can you say of the general results of your experience in climato-therapy?'

"Answer. I think I have said enough already. As to the comparative results obtained, I believe the system hinted at in the foregoing answers is the correct one. I refer to individualizing each separate phthisical patient, and differentiating his disease, with a view to determine if he can and will make the fight required to get well in proper high altitudes, and if, *for that at present*, he ought not to resort to such a climate as that at the eastern Rocky Mountain base,

then to compromise on the next best climatic change possible. I believe, from my own experience, that such a system will give much better results than are obtained by many physicians who send most of their patients to warm, moist, and sedative climates. Of course, there are many difficulties; for we learn, at last, that what is an *ideal* climate for one consumptive is not so for another. There are sometimes difficulties as to diagnosis, personal idiosyncrasies of patients, pecuniary embarrassments, etc., which may amount to insurmountable barriers; but, to my mind, the fact yet remains to be gainsaid that climate is the most potent means known at the present time with which to combat this destroyer—consumption."

6. FAR INLAND (CONTINENTAL).

Moderate dryness. Prevailing temperature—cool and cold.

MINNESOTA.

Dr. Talbot Jones, St. Paul: "It is undoubtedly true that the vast majority of climatologists maintain—and they reflect the general sentiment of the profession on this question—that the more nearly a temperature approximates to equability and uniformity, the more nearly it approximates to an ideal climate for consumptives. As I can not concur in this view, it may be well to state the reasons for my dissent. Man's proximate immunity from pulmonary consumption is observed under two separate and distinct conditions of life—modifications of temperature have to do with one, degrees of altitude with the other. With regard to the first, it may be said that it is now definitely settled that the death-rate from phthisis progressively decreases from the tropics to the poles, and that proximate immunity is found in the frigid regions.

"With regard to the second, it appears, from an extensive series of data which is so convincing as now to be no longer questioned in any quarter, that the greatest death-rate from consumption occurs in localities with but slight elevation above the sea, and that this mortality steadily decreases the higher we ascend the mountain elevation, until a certain height is reached (differing according to latitude), when proximate immunity again is observed.

"Man's proximate immunity from pulmonary phthisis, then, is found only *in frigid regions* on the one hand, and *at considerable altitudes* on the other; and in neither of these positions is *equability of temperature* ever observed. Fluctuations of temperature are an invariable feature of the climate of both high altitudes and cold regions. Or, to state it differently, variations of temperature are characteristic of the climate of those localities where alone pulmonary consumption is infrequent or unknown.

"The converse rule is equally true; the maximum mortality from the disease is observed in those localities the climates of which are constant and equable, as, for example, the West India Islands, Brazil, and Sierra Leone; and Fuller (London 'Lancet') has shown that the death-rate from consumption in Spain, France, and Italy, bordering on the Mediterranean Sea, with their sedative and uniform climates, is greater than that observed in England itself with its variable atmosphere.

"The preponderance of opinion at the present time among those who are regarded as our best authorities on climatology is that a so-called *sedative* climate is too often a delusion, is in no sense curative of consumption, and that such climates should generally be avoided. With this opinion my own is in perfect accord. I base my objections to such climates partly upon clinical experience, but principally upon the following considerations (taking Nassau as an example): (a) Such resorts usually are of but slight elevation above the sea; (b) the atmosphere generally is surcharged with moisture, and fogs abound; (c) the atmosphere is not sufficiently aseptic; (d) the skin, which is a supplementary organ of the lungs in ridding the economy of effete matters, does not properly functionate in a sedative climate; (e) there is great relaxation of the muscular system, with resultant deficient bodily exercise; (f) oxidation of the tissues in such climates is reduced to a minimum, as shown by the decreased amount of carbonic-acid gas thrown off from the lungs; (g) such climates are too often hot and enervating, spoiling the appetite and depressing digestion and assimilation; (h) our chief therapeutical reliances in the arrest or cure of phthisis—oils and fats—are, in sedative climates, disgusting to patients, and can scarcely ever be taken; (i) a sedative, or hot and moist, climate can not but play the rôle, so to speak, of an internal poultice on crude tubercle, promoting its liquefaction and extrusion; (j) finally, the maximum death-rate from pulmonary consumption, both in this country and in Europe, is always observed in sedative climates. (Pollock, London 'Lancet'.)"

"I favor a 'stimulating, tonic—a so-called *sthenic* climate, as found at certain far inland stations at medium or high altitude, not reached by the moisture from the ocean or large lakes—such as Minnesota, the eastern slope of the Rocky Mountains in New Mexico and Colorado. . . ."

"The 'National Board of Health Bulletin' (Washington) states that the annual death-rate per 1,000 inhabitants is 1.84 in the Northwest, with its sudden fluctuations of temperature, and 3.74 in the Southeast, with its equable and uniform temperature.

"I do not wish to be understood as claiming that man's immunity from consumption in cold and high regions is owing to the variable climate, or the great mortality observed in sedative climates to its absence; nothing could be more absurd; but I think the significance of these facts has not been dwelt upon sufficiently by systematic writers on climatology.

"The practice of recommending sedative climates to patients the subject of phthisis pulmonalis, which almost universally obtained fifteen years ago, has, within the past few years, been in a great measure abandoned, and the general sentiment of medical authors at the present time is that those resorts are best which are cool or cold, with considerable elevation above the sea. Along with these recommendations, however, and often even in the same sentence, is the requirement that the climate of such resorts shall be free from atmospheric variations.

"Now, I make the statement, with the utmost confidence in its correctness, that no resorts can be found in any zone

which are at once elevated and cold, the climate of which is uniform and equable.

"Coldness and variability of temperature are indeed interchangeable terms, as are elevation and variability. To admit the one presupposes the other.

"Hence the inconsistency of physicians' advising patients to visit resorts of moderate or great altitude, the climate of which is cold and also equable, as though such a resort could really be found.

"Yet this is done by a great many authors.

"For instance, Flint, in his 'Practice of Medicine,' speaking of the climatic treatment of pulmonary tuberculosis, says (referring to Minnesota): 'Were it consistent with the limits of this work, I could cite some cases which are strikingly illustrative of the salutary influence of the *uniform*, dry, cold atmosphere of that northern region.'

"The concurrent testimony of the salutary influence of the climates of Minnesota, Colorado, and New Mexico on pulmonary phthisis is very great; but the benefit derived is not to be attributed to a supposed uniform temperature, for it has been shown they do not possess this, but must take place, notwithstanding a variable temperature. The medical profession, I state with diffidence, must either cease recommending the climate of New Mexico, Colorado, Minnesota, and others that are cold and elevated, or they must abandon their objections to climatic variations.

"I do not wish to be understood as advocating cold climates with moderate altitude because they are subject to fluctuations of temperature, but rather as advocating them notwithstanding these fluctuations, the harmful effects of which I believe to be exaggerated.

"If a climate could be found of *moderate altitude, cold and reasonably uniform*, such a one would, in my opinion, approximate to an ideal climate for the vast majority of cases of catarrhal phthisis."

THE BICYCLE AND TRICYCLE FOR PHYSICIANS AND PATIENTS.

By CHARLES A. KINCH, M. D.

THE parade of nearly nine hundred bicycles and tricycles in New York, about a month ago, and the opening of Central Park for riding on them at certain hours of the day, turn afresh the minds of the people and the profession to the merits of these instruments.

In England and Ireland the use of the bicycle is quite common among professional men, clergymen making their parochial calls, and doctors their professional ones, by its aid. Some physicians turn their horses out to grass in the pleasant season, and others keep but one, supplementing his work by a well-selected bi- or tricycle. The number of those who use these machines in Great Britain is estimated by "tens, perhaps hundreds, of thousands" ("Brit. Med. Jour.," 1878, vol. ii), and the number in the United States and Canada is thought to exceed twelve thousand. The League of American Wheelmen was organized in 1880, "to promote the general interests of bicycling," and its membership is being rapidly recruited—the advantage of its

store of information concerning the best roads, and the rights of wheelmen, being apparent to every one who rides.

The bicycle is a wheel supporting a saddle, upon which the rider sits erect and evenly balanced, just behind a vertical line drawn through its axis. The wheel, having cranks at the extremities of the axle, is propelled by the foot with a motion analogous to walking. The machine is guided by means of a handle-bar, about two feet in length, placed conveniently in front of the saddle, transversely to the line of motion. A small following wheel bears a part of the weight. Only when in motion can the upright position be maintained.

It is evident that the size of the wheel is limited by the length of the rider's leg. A man of average weight and height, whose "leg-measure" (from perineum to sole) is thirty-three inches, will ride a wheel of fifty inches diameter, or seventy-eight and one half inches half-circumference. The same man in walking will take a thirty-inch step. With every tread on the wheel he advances two and a half times as far as in walking. In walking, too, the weight is supported by the legs; on the wheel by the pelvis. The advantage of momentum is more direct in the new mode of progression. "Only during about one third part of the journey is the machine propelled by the rider's own power. On the level, the muscular exertion is almost *nil*, and on a decline absolutely *nil*—the body is resting. Hence it is left for the inclined part only of the road for real work. And here, again, if the hill be steep, the muscular power is saved, in that it is varied by a dismount and a pleasurable walk to the top" (W. W. Hardwicke, "Brit. Med. Jour.," 1882, vol. ii, p. 244). The theory is more than realized in practice. Mr. A. S. Parsons, when a beginner, wrote: "In going back and forth from my house to business, I made the distance easily in eight or nine minutes, which the fastest walking can only cover in twenty minutes, and for the first time in my life wished it was longer." "A country surgeon" ("Lancet," 1874, vol. ii, p. 145) says: "My usual pace is ten miles an hour." Mr. W. W. Hardwicke (quoted above) says: "Practical experience teaches me that I can ride from fifty to seventy miles a day, and carry a reasonable amount of luggage without much fatigue."

The bicycle has covered a mile in 2.42, and made twenty miles within an hour. ("Bicycling World Supplement," April, 1883.)

Every summer witnesses an increasing number of touring bicyclists, who, ignoring railroads and despising horses, make trips as far as to Boston and return, spending their vacations in this way. Riding at leisure, and stopping at will, they gain the most intimate acquaintance with the country they traverse and the people they meet.

Concerning the moral tendencies of bicycling, it is sufficient to say that no sport can be more antagonistic to the vice of drinking than this. For few take an interest that are not practical bicyclists. In fact, the fascination is irresistible. One must learn to sit, and riding requires a steady head. No gambler need but remember the saying:

The character of the exercise which bicycling affords is well described in an article, "The Effects of Bicycling on the Health," in "Physician and Patient," April, 1880.

It is too long to quote here, but the substance is this: that "the exercise is varied and well distributed," and "taken in the open air and sunshine." It strengthens the arms and broadens the chest. It develops the muscles of the back, loins, and legs. If through too long riding, or exposure to a draught of air when heated, the rider is lame, he is lame in every part. Arms and legs and back are alike affected.

A few years ago, it was noticed in England (for they have been riding longer there than here) that many cyclists were afflicted with hernia. This led to the inquiry whether the exercise favored the production of this malady. Robinson has reported a case ("Lancet," 1882, vol. ii, p. 472) in which a competitor had to be lifted off his machine. The hernia was easily reduced, but he was violently sick. Very many letters were written to the "Lancet," almost unanimously expressing the opinion that it did not favor or induce rupture. Indeed, three cases of ruptured persons riding, and under the observation of qualified medical men for a considerable time, were detailed ("Lancet," 1879, vol. ii, p. 968; *ibid.*, 1882, vol. ii, p. 337.)

Racers and hill-climbers are found to suffer from varicose veins, and this subject has been discussed in the British journals. The pith of the discussion is given in the following words of Mr. John Lowe ("Brit. Med. Jour.," 1881, vol. ii, p. 144): "I deny that bicycling can produce a varicose condition of the veins of the leg without a pre-existing tendency in the man to become varicose. Given this tendency or diathesis, moderate bicycling will strengthen the coats of the veins in proportion as it improves the general health; but, the moment moderation is exceeded, an element of danger usurps the place of safety." Mr. C. W. Robinson says (*ibid.*, 1882, vol. ii, p. 472): "It is most noticeable in those who do any large amount of running or walking." Mr. Robinson also calls attention to the fact that "varicose is made worse if the person so affected take an undue amount of exercise, but not so under any moderate amount."

Bicycling may be prescribed for many to whom horse-back riding would be advisable. The bicycle has this prime advantage over the horse, that it is not owned and operated by a separate intelligence. The machine is under the rider's perfect control. He may ride fast or slow, easily or with effort.

The accidents which befall cyclists are few and trifling. They occur mostly to learners and racers. An instructor in this city of much experience told the writer that he knew of but one man who had been seriously injured. He was an enthusiast, fifty years of age, who, as soon as he unboxed his new machine, mounted it at the top of an incline, contrary to instructions, and it ran away with him. Putting on the brake suddenly, he found himself several yards in front of his wheel, with multiple fracture of the forearm.

When the wheel meets with any obstruction upon the road, either unobserved by the rider or thrown by some mischievous urchin, the rider is pitched forward upon his hands and knees, in the same way as if he had stumbled while running upon his feet. This is called "taking a header." The wrist is sometimes sprained in these involuntary dismounts, but the rider is never seriously injured, unless he is going at an inordinate rate of speed.

There are machines of peculiar construction, in the use of which, it is claimed, "headers" are impossible.

The tricycle can not become popular in this country until our roads are brought more nearly to a state of uniform perfection. This consists of two wheels, side by side, between which the rider sits and propels them by a crank motion with his feet. A third, or steering wheel, is placed either in front or behind. In England they are fitted up for physicians' use with lamps, bells, pouches for drugs or instruments, and umbrella-sockets. A considerable correspondence in the "British Medical Journal," 1882, vol. i, indicated that the average speed of these machines was seven miles an hour. "At the Hammersmith Police Court" ("Brit. Med. Jour.," 1882, vol. ii, p. 825) "a Fellow of the Royal College of Surgeons appeared to answer a summons for furiously riding a tricycle, and was fined. . . . When a mounted constable has to gallop his horse to overtake a tricycle, it is obvious that the tricycle in question is going at a rate exceeding six miles an hour." Mr. Westropp writes ("Brit. Med. Jour.," 1879, vol. i, p. 795): "I can travel eight miles an hour, and can ride thirty or forty miles with enjoyment and little fatigue."

The tricycle is available for ladies. Recently a woman is reported to have traveled from Liverpool, Eng., to Newcastle and back, a distance of one hundred and two miles, in sixteen hours and a half. But more moderate use of this vehicle by ladies, whether in good health, or semi-invalid, or crippled, is to be commended. Mr. Arthur Kempe ("Brit. Med. Jour.," 1881, vol. i, p. 582) and a correspondent signing himself "Nestor" (*ibid.*, p. 539) advocate the tricycle for females to whom gentle out-door exercise would be advantageous.

The only expense of a bicycle or tricycle is its first cost. A bicycle costs from \$100 to \$160. A tricycle costs from \$135 to \$180. They are made chiefly of steel, with thick rubber tires. It requires no feeding or shoeing of horses, and is always ready.

The comfort and pleasure which well-fitted glasses give to ametropic eyes can not be told in words; no more can be revealed, to one who has not tried, the value of a machine which multiplies his locomotive powers by three, and transfers a due proportion of the work he does from his lower to his upper limbs.

256 WEST FIFTY-FOURTH STREET,

June 18, 1883.

Clinical Reports.

WOMAN'S HOSPITAL.

Reported by JAMES R. GOFFE, M. D.

(SERVICE OF DR. THOMAS ADDIS EMMET.)

LACERATION OF THE PERINÆUM AND CERVIX UTERI; OPERATION; SECONDARY HÆMORRHAGE FROM THE CERVIX.

MRS. MARY P., aged thirty-three, a native of Ireland; married fifteen years, has had seven children; the first child fourteen years ago, the last two years ago. All confinements slow and tedious; the first and last two deliveries were instrumental.

Never had a miscarriage. Has suffered since birth of the last child with pain in left-side and back; has been greatly annoyed at times with frequent and painful menstruation. Laceration produces dragging pains across the lower part of the abdomen and in the back; tires easily. On examination, there was found a laceration of the perineum down to the sphincter, a laceration of the cervix to the vaginal junction on the left side, and a chronic endo- and perimetritis. Patient entered the hospital April 15, 1882, and was put at once on hot-water treatment, with iodine applications to the vaginal wall twice a week, and glycerin pack, rest, and nourishing food. Patient improved rapidly under treatment, and the double operation, closing both cervix and perineum, was done June 7th. There was an unusual amount of hemorrhage from the cervix during the operation, but, after the sutures were passed, everything was considered secure and the patient was put to bed.

During the night it was discovered that the patient was having quite a profuse hemorrhage from the vagina. Alum douches were given repeatedly, which diminished the hemorrhage, but did not control it. The following morning there was a steady oozing of blood between the labia, and examination discovered the vagina filled with clots. The patient was blanched and weak, and evidently greatly exsanguinated. It was apparent at once that an artery was involved, and something decisive must be done. The patient was placed on the table in the Sims posture, the perineal operation taken down, leaving the wires in place, the speculum placed, the vagina cleaned, and the cervix wires removed. High in the angle of the wound was found a little spurting artery. This was controlled by passing two deep sutures well up in the angle. The operation was then completed as before, the perineal wires were twisted, and patient was put to bed. She was too weak to be anesthetized, but bore the operation well under the influence of π viij of Magendie hypodermically.

Patient progressed well till June 11th, when she had a severe chill about midday. Pulse 140, temperature 104°. Quinia, nourishment, and stimulants were administered regularly per rectum, and no other unfavorable symptoms occurred.

June 13th. Pulse and temperature normal. Perineal and cervix stitches were removed, respectively, on June 17th and 24th. The secondary operation had not impaired in the least the perfect union of the parts. Patient discharged cured.

The case is instructive from the fact that nothing short of what was actually done could have controlled the hemorrhage, the fact that the secondary operation did not interfere in the least with the healing process, and a perfect result, notwithstanding the greatly reduced condition of the patient caused by the hemorrhage.

Book Notices.

Speech and Its Defects, considered Physiologically, Pathologically, Historically, and Remediably. By SAMUEL O. F. FETTER, M.D., author of "An Index of Comparative Therapeutics," etc. Philadelphia: P. Blakiston, Son & Co., 1888. Pp. 117. [Len Prize Thesis of Jefferson Medical College.] [Price, \$1.]

With the exception of the elaborate article by Kussmaul in von Ziemssen's "Cyclopædia," there is no really scientific and authoritative work upon this subject in the English language. The author of the book before us, therefore, has had an exceptional opportunity. He divides the subject into three principal heads—*Alalia*, *Paralalia*, and *Dyslalia*. Six pages are devoted

to a consideration of the first two, while the latter subject—stammering and stuttering—monopolizes the remainder of the book. It is practically a thesis on stammering by one who, like most students of the subject, has for years been a stammerer himself. The present reviewer, writing from the same standpoint, is glad to welcome the well-considered views and really valuable advice with which the book abounds. Leaving the introductory and historical part, and turning directly to the pathology of dyslalia, the author states that "in all forms and varieties of the disorder the essential condition present is *spasm* of a greater or less degree, which necessarily implies deranged nerve function." This spasm may occur at various points in the vocal tube, and by its continuance a spasmodic habit is acquired which, becoming more and more automatic, produces at last confirmed dyslalia, "perhaps by the resulting vicious automatism of some nerve center not yet located, which may preside over the co-ordination of the movements of speech alone." That the ordinary center for the co-ordination of muscular action is affected he does not believe.

As to the etiology of stammering, various predisposing causes are enumerated. The chief proximate causes are: 1. Nervous excitability. 2. Debility after disease. 3. Peripheral irritation. To these are added imitation and mental expectancy. As explaining the remarkable and well-recognized fact that stammering is far more common in boys than in girls, the author holds that, in childhood, the girl is under the maternal influence, while the boy, subject to the influence of the father, is, therefore, exposed to that severity of treatment which, in his belief, is the most fruitful source of stammering. We have been at some pains to investigate the soundness of this view, and fail totally to see the truth or justice of it. The paternal influence is by no means invariably harsh, nor is the girl always under the influence of a gentle mother. Moreover, at large charitable institutions, where the children are constantly under female supervision, the same relative frequency among boys exists.

"Very few cases are incurable if the proper treatment be commenced in early or middle life, and steadily persevered in for a sufficient length of time. . . . Probably weakness of the will power is the most unfavorable symptom, as preventing sufficiently arduous application."

The course of treatment generally recommended at the present time may be summarized as: "1. Disciplinary exercise of the respiratory, vocal, and articulating organs, conducted unremittingly, until a correct habit of speech is established, and aided by the use of the utmost degree of will power of which the patient is capable. 2. Treatment directed to the correction of special symptoms and the general health while the vocal treatment is in progress." These principles are elaborated at length, and many valuable suggestions given in connection with them. An exhaustive bibliography finishes the book. Taken as a whole, the work is an earnest, sincere, and successful effort toward the relief of a distressing and much neglected class of cases, and as such we extend to it a cordial recommendation, and wish for it the success which it deserves.

Observations on FEVER, SCARLET FEVER, and SMALL POX, MADE BY W. WYKES, M.D., SURGEON OF THE (MILITARY) MEMORIAL HOSPITAL, SHANGHAI; PRINTED AT THE STATISTICAL DEPARTMENT OF THE INSPECTORATE-GENERAL OF CUSTOMS, 1881. [Pamphlet.]

This treatise on *fever* was originally prepared as a *handbook* for the use of the *Medical* and *Natural* History Society, and was published by the *Statistical Department of the Inspectorate-General of Customs*, 1881, and which achieved much popular notoriety through Manson's subsequent observation that the mosquito acted as its

intermediate host, has presented to pathologists a perplexing problem in the sudden appearance and disappearance of its embryos in an infected person's blood, which, after swarming with them during the night, will be free from a single specimen by breakfast time, and again display them in increasing multitudes at eventide. Dr. Manson's suggestion, that the embryos may lie hidden in the lungs or some other central depot throughout the day, preparing for their nocturnal excursions into the systemic circulation, is unsatisfactory from a physical point of view, and is, moreover, based upon examinations of infected dogs, in which animals the blood parasite is at all times present, leading Lewis and Cunningham to the opinion that the canine filaria may specifically differ from that of the human subject. To settle this and other moot questions, Dr. Myers recounts a series of experiments, conducted with rather scant materials, since, notwithstanding the frequent intercommunication between Amoy, where the filaria disease prevails, and Formosa, he could find but three "filariated" persons in the latter place. Two of these, though their blood showed numerous embryos at night, were free from enlarged glands, or "any other ailment which might be attributed to filarial infection"; the third, upon whom the author's observations were chiefly made, was a man who, beyond a long-standing slight enlargement of the inguinal glands and occasional "ague" with little rise of temperature, was "in good health and doing his daily duty." Frequent inspections of this patient's blood showed that the embryos regularly made their appearance between 6 and 8 P.M., attaining their maximum number by midnight, and thence gradually decreasing until they entirely disappeared between 6 and 8 in the morning. Mosquitoes made to feed upon this man's veins were found to have digested instead of nurturing the filariae which they extracted, and monkeys forced to drink water wherein their ova were deposited exhibited no signs of filarial infection; whence Dr. Myers infers that the Amoy mosquito is of a different species from that of the mainland, which seems to have been convicted of harboring and transmitting the parasite. It is noteworthy in this connection that Dr. Manson had already stated that the man-infesting mosquito destroyed and digested filarial embryos obtained from the dog.

From numerous microscopical examinations of blood withdrawn at short intervals from the circulation of his unique patient, the author reaches the conclusion that the embryo filariae are dissolved after the brief preliminary stage of their life-cycle, and that the parent worm (or worms), lying-in in some convenient lymphatic gland, may give birth to fresh myriads of progeny every night. The limited field of these observations renders them of doubtful scientific value; but they are not without interest as tentative contributions to the literature of a puzzling biological question.

Syphilis. By V. CORNIL, Professor in the Faculty of Medicine of Paris, etc. Translated, with notes and additions, by J. HENRY C. SIMES, M.D., Demonstrator of Pathological Histology in the University of Pennsylvania, etc., and J. WILLIAM WHITE, M.D., Lecturer on Venereal Disease, etc., in the University of Pennsylvania, etc. Philadelphia: Henry C. Lea's Son & Co., 1882. Pp. 461.

In editing another man's book, as in restoring works of art, there is great liability of the work being overdone.

It is a little strange that the translators of M. Cornil's book, after a lapse of less than four years since the original was written, should have deemed it necessary to increase the matter to such an extent as "to aggregate one third of the present volume." One can but suppose either that Cornil's work was singularly defective, or else that the translators have greatly

modified the author's scope and intention. The latter alternative appears to us the more tenable. It has been the editors' aim, apparently, to make the work more serviceable as a clinical text-book, to give it more the character of a general treatise. That such an aim was foreign to the author's design is evident where in his preface he says: "It is not my intention to publish a complete treatise, but only a series of lectures upon the essential points of syphilis, and particularly upon its pathological anatomy." Regarded as a contribution to the pathological anatomy of syphilis, Cornil's work is magisterial. The attempt of the editors to make the work serve as a general hand-book on syphilis, so as to compete with the numerous excellent general treatises already before the profession, we can not but regard as a mistake. A complete treatise, in which the high standard of the distinguished author was applied to every department of the subject, could scarcely be compressed within four times the space of the volume before us.

With a few exceptions, we have little fault to find with the additions that have been made, taken by themselves. As far as they go, they appear to us in the main to be judicious and valuable. Notably in connection with the differential diagnosis of syphilitic from other affections, the tabulated diagnostic points, whether original or compiled from other writers, are well stated, and for clinical instruction would be very useful. Several of the additions serve as valuable commentaries upon the text. We think, however, that most of them would have appeared better were they inserted as foot-notes, whereby the continuity of the original would have been preserved, which now, in several instances, has been sacrificed. Moreover, we can not but regard the interpolation in such a work as Cornil's of unsubstantiated theories of pathology for which the editors happen to have a predilection as in the nature of an intrusion. While a conservative allusion in a foot-note to the peculiar views of various writers would neither encumber the book nor be liable to mislead the reader, the devotion to these views of several pages of the author's text, with nothing to mark their extraneous character but small brackets at the beginning and the end, appears to us decidedly unwarrantable.

Ueber die primären chronischen Erkrankungen des willkürlichen Bewegungsapparates. Von Dr. PAUL JULIUS MÖBIUS in Leipzig. Leipzig: Georg Böhme, 1882. Pp. 16.

THE purpose of this little pamphlet is to draw attention to a group of symptoms confined to the voluntary muscular apparatus (progressive muscular atrophy), the expression of changes in the spinal cord. The pathological changes have been described under the following name:

I. Atonic progressive muscular atrophy.

a. A simple or peripheral form of progressive muscular atrophy:

1. A simple, progressive muscular atrophy of adults. 2. A hereditary progressive muscular atrophy, with or without "lipomatosis."

b. A central form of atonic progressive muscular atrophy:

1. A spinal form. 2. A bulbar form. 3. The bulbo-spinal form.

II. Spastic progressive muscular atrophy:

1. A spinal form. 2. A bulbo-spinal form.

In a pamphlet of only eleven pages it is impossible to treat the subject with any degree of satisfaction. Indeed, the author only considers the most prominent symptom connected with these pathological conditions, namely, the behavior of the muscles. A review of the pamphlet is not called for. We can only draw attention to it and to the fact that the author has been able to condense a great amount of information within a small

space. It will be of use to one who has not the time to study the subject in the larger and more thorough treatises on progressive muscular atrophy.

Physical Education; or, the Health Laws of Nature. By FELIX L. OSWALD, M. D. New York: D. Appleton & Co., 1882. Pp. 257.

The author has produced in this a very readable book. It is semi-scientific, and somewhat after the style of Fothergill's book of about the same size, "Laws on the Maintenance of Health." The book gives directions as to diet first. The author announces himself as almost a vegetarian, considering a vegetable diet the nearest to the natural. Although his directions as to children's diet are in the main good, they give evidence of his being a theorist rather than a practical physician. The author takes pleasure on every possible occasion in having his fling at religion and its accompaniments. In fact, he is sacrilegious at times. Gymnastics and out-of-door exercise are favorably commented on. He is very skeptical on the subject of the treatment of disease by medicines. A very practical chapter on clothing, another on sleep, and one on recreation—all three contain many valuable hints. A chapter on "popular fallacies" closes the book, which is more fit for the non-medical than the medical reader. While there is much in it which might excite much adverse criticism, it contains many valuable hints.

On Asthma: its Pathology and Treatment. By HENRY HYDE SALTER, M. D., F. R. S., F. R. C. P., Physician to Charing Cross Hospital, etc. First American from the last English edition. New York: William Wood & Co., 1882. Pp. xii-284. [Wood's Library of Standard Medical Authors.]

It is hardly necessary to call the attention of the profession to Hyde Salter on asthma. Every medical student probably, during his first year, has seen or heard some reference to it. Nor is it strange, for Dr. Salter has done more, perhaps, than any one man to enlighten us on the subject. While on many points, especially in the pathology, late observations have apparently shown Dr. Salter to be in error, in the main his views are accepted. Any medical man who has studied this curious disease can not have failed to become much interested in it, and any one who has become interested in it must have read Salter. He was himself a sufferer from the disease for many years. Many of the now accepted facts in regard to the disease, particularly concerning its clinical history and treatment, were first brought out by him.

No reference is made in the book to the treatment of the paroxysm by hypodermic injections of large doses of morphia. The author has made some very interesting additions in this edition in the way of cases of uterine asthma.

At the end of the book there is a very valuable tabulated list of cases, 223 in number. We can simply say of the book, no physician can afford to be without "Hyde Salter on Asthma."

The Functions and Disorders of the Reproductive Organs in Childhood, Youth, Adult Age, and Advanced Life, considered in their Physiological, Social, and Moral Relations. By WILLIAM ACTON, M. R. C. S., late Surgeon to the Islington Dispensary, etc. Sixth edition. Philadelphia: P. Blakiston, Son & Co., 1883. Pp. xii-267.

This book is too well known to need an extended notice. Dealing as it does with a most delicate subject, the author treats it from the stand-point of the physician, as well as that of the moralist. Though there are numerous details which might well

have been omitted, judging the book from a semi-scientific standpoint, it is interesting and instructive.

The changes in the present edition are not important, and the reader still recognizes the manly tone which has always pervaded the author's works. We do not hesitate to re-echo his wish that the book "may continue to exert some good practical influence upon public health and public morals."

Congrès international de laryngologie, 1^{re} session, Milan, septembre, 1880. Compte-Rendu publié par CHARLES LABTA, Président du Congrès, sur les propositions de l'Assemblée par le secrétaire, M. FRUA. Milan: Pierre Agnelli, 1882. Pp. vii-255.

To the editor of this work belongs the credit of having originated the idea of an international congress of laryngology. No higher tributes to its success could be offered than the extraordinary number of distinguished specialists who attended, the number and importance of the papers presented, and the fact that the congress has assembled every year since. To mention the titles alone of the forty-four papers read would exceed the limits of this notice. Fortunately, the more important ones have since appeared, in one form or another, in the various journals, so that the practical knowledge brought out by the meeting has been generally distributed. The complete Report is a work of great interest and value—a worthy monument to the devotion, the energy, and the general popularity of the distinguished and much-esteemed president of the convention.

BOOKS AND PAMPHLETS RECEIVED.

Hospitals, Infirmarys, and Dispensaries: their Construction, Interior Arrangement, and Management. With descriptions of Existing Institutions and 74 Illustrations. By F. OPPERT, M. D., M. R. C. P. L. Second (English) edition, revised and enlarged. London: J. & A. Churchill, 1883. Pp. xviii-1 to 278, inclusive.

Natural Cure of Consumption, Constipation, Bright's Disease, Neuralgia, Rheumatism, Colds (Fever), etc. The Origin, Prevention, and Removal of Disease. A Manual of Hygiene for Well and Sick. By C. E. PAGE, M. D. New York: Fowler & Wells, 12mo, extra cloth. Pp. 278. [Price, \$1.]

Bad Elster in Sachsen. Eine Darstellung alles Wissenswerthen für Kurgäste und Freunde des Bades. Neun Briefe an einen Freund, von Dr. Hermann Helmkampff, Badearzt in Elster. Berlin: Eugen Grosser, 1883. Pp. v-72.

Medical Society of the State of Tennessee. Transactions, 1883. Fiftieth Annual Meeting. Nashville, 1883. Pp. 104-ii.

Woman's Medical College of Pennsylvania. Philadelphia. Thirty-fourth Annual Announcement, May, 1883.

The Second Annual Announcement of the College of the Woman's Medical College of Baltimore, for the session 1883-'84.

One Hundredth Annual Catalogue of the Medical School (Boston) of Harvard University, 1882-'83. [Reprint from the Catalogue of the University.] Cambridge: Charles W. Sever, 1882.

New Hampshire Medical Institution. Eighty-seventh Annual Course of Lectures of the Medical Department of Dartmouth College, Hanover, N. H. Announcement for 1883.

University of the City of New York. Medical Department. Forty-third Annual Announcement of Lectures and Candidates. Session 1883-'84.

Thirty-seventh Annual Announcement of Starling Medical College, together with Catalogue and Order of Courses and Hospital Exercises for the Session of 1883-'84. Columbus, Ohio.

NEW YORK, SATURDAY, JUNE 30, 1883.

RECENT MEDICAL LEGISLATION IN MICHIGAN.

THE notification of infectious diseases has been made compulsory in Michigan by an act which requires physicians to give immediate notice to the Board of Health of the occurrence of cases of small-pox, scarlet fever, diphtheria, cholera, or any other infectious disease, in their practice, like notification being required of heads of families also in regard to cases of those diseases occurring in their own family circles. Without having seen the full text of the law, we take it that the notification must come either from the physician in attendance or from the head of the family, not from both. The physician would doubtless be held responsible, however, provided one had been employed, the alternative requirement being left to apply only in the case of families that dispensed with medical attendance on the occasion. Strictly speaking, indeed, it is not the head of the family, but the householder, on whom the requirement falls; so that keepers of lodging-houses and the like are responsible for the notification of cases occurring on their premises, even in the person of a stranger.

Stringent as this requirement may seem, it is none too exacting in the interest of public protection. It is difficult to see, however, that its frequent evasion is to be prevented, for nothing would be easier than for the householder to profess ignorance as to the nature of the disease, relying, as he well might, on the general disinclination of juries to hold an accused person to strict accountability in matters involving questions of judgment. The law provides for the payment of a fee of ten cents for every such report made by a physician. While not bountiful enough to inspire too much zeal in diagnosing cases of disease to be of a character to fall within the provisions of the act, it is a recognition of the principle that no unrequited service should be exacted of a citizen.

Along with this careful provision for the notification of infectious diseases, it is to be regretted that the work of collecting, arranging, and publishing the vital statistics of the State is taken away from the Board of Health, and vested in the Secretary of State, by whom, it is to be feared, the task will be delegated to assistants incapable of anything higher than clerical work. It is difficult to set too high an estimate on the value of accurate and well-arranged vital statistics to a community, and it is equally difficult to overdraw the errors that may result from negligence or ignorance in the preparation of statistics.

The powers of health officers are made commensurate with their multifarious duties, but their compensation, we regret to see, is provided for at the aiggardly rate of "not less than two

dollars a day while actually employed." What sort of service can the State of Michigan expect for this trivial remuneration? The law charges individual health officers with duties and powers demanding great discretion and no little intelligence. To look for creditable work without providing more than the paltry rate of payment we have mentioned seems exceedingly shortsighted.

The act for the regulation of the practice of medicine within the State makes it unlawful to practice without having registered at the County Clerk's office, besides which those who have not been in practice in the State for five years continuously must be graduates of some legally authorized medical college. These provisions, it will be seen, are not materially different from those in force in the State of New York. We wish we could add that they seemed at all well calculated to bring the profession up to a proper level. If anything is to shame the State of New York into enacting laws that shall protect its citizens from quackery and incompetence, it is likely to be the example of other States. Illinois having made some approach to the necessary example, it seems to us very much to be regretted that Michigan has not chosen at least to advance as far.

THE POPULAR ESTIMATE OF THE CRIMINALITY OF INDUCED ABORTION.

THE neighboring city of Philadelphia has lately been startled at a ghastly array of revelations implicating one Hathaway in a career as an abortionist almost if not quite unparalleled in the revolting annals of feticide. The cellar of a house he had occupied has been found to be paved, so to speak, with the mangled remains of fetuses, together with those of children that were viable if not actually born alive, the theory being that the latter were murdered methodically by this octogenarian monster.

It seems to be quite by chance that the main facts have been brought to light, Hathaway's reputed wife having quarreled with him, and having in her resentment, coupled, let us hope, with something of remorse, given information to the police. The woman's story receives circumstantial confirmation in the shape of certain admissions by a son of Hathaway's, consisting largely of horrid reminiscences of the use to which the old man put the house-dog—that of wiping out the tangible evidence of his crimes by devouring the flesh of the victims.

Although the woman accuses the prisoner of having practiced his vile art upon her own person, and although the newspapers seem hopeful of proving other specific cases, the history of prosecutions for criminal abortion scarcely warrants any confident expectation that individual acts can be brought home to the man Hathaway in such a way as to insure legal punishment at all commensurate with his evident course of crime. But, even should our anticipations be happily disappointed, for what will the wretch be punished? What sentiment will guide his prosecution? It will not be horror at the abstract wickedness of abortion, if we may judge by the estimate commonly placed on that offense, but rather horror at the shocking accessory facts. We do not doubt, indeed, that the actual officers of

the law will take the case in hand with a proper appreciation of the enormity of the fundamental sin—spurred on, perhaps, but not blinded, by the side issues; our reference is to the popular sentiment, the feeling that inspires the making of laws, and that nerves judge, jury, and prosecuting attorney to their due enforcement.

The popular conception as to the criminality, or rather the sinfulness, of *abortion procuratio* is almost as varied as the individuals that make up the community, ranging from mere aversion to being "found out," through the progressive grades of horror when the death of the woman is the result, when the *fœtus* has shown a degree of "life" that has been manifested by independent motion, and when an actual *fœtus* at any stage of its development has been sacrificed, up to the twinge of conscience that a few men of fine moral organization would feel at the thought that they had been at all instrumental in preventing a conception, let alone the wanton destruction of its legitimate product.

With all these distinctions, many men would—so they freely avow—recoil not from the act, whatever their idea of its sinfulness, so long as the woman who sought "help" was a dear relative, or one in whose transgression they themselves were not free from complicity. "Self-preservation," they would complacently plead, "is the first law of nature!" While we can not deny that there are many medical men who would condone such a stifling of conscience, even if they did not lend material aid and comfort to the persons concerned, we yet regard it as one of the proudest claims of our profession upon the gratitude of all right-minded persons that, as regards the overwhelming majority of its members, it has ever, from the time of Hippocrates until now, frowned relentlessly upon all such casuistry, and spurned the tainted gold tendered as the reward of complacence.

CRIMINAL ABORTION *IN POSSE*.

In the foregoing article we have hinted at a phase in which criminal abortion undoubtedly presents itself to a very few persons. We refer to the sense of criminality that a sensitive conscience would feel at having connived, however remotely, at the commission or suggestion of any act or course of conduct which, although not aimed at the destruction of a life already begun, should have been adopted with the intention of preventing that life from coming to pass.

We are quite aware that the great majority of persons, even among the reflecting and the reputedly moral part of the community, will, far from assenting to our position, look upon it as strained and transcendental. We should be surprised, indeed, to find one woman, unless educated in medicine, agreeing with us, for in this matter the ordinary conscientiousness of the sex is warped and twisted out of its symmetry by selfish considerations, unconsciously no doubt, but none the less certainly. Many a woman who in all other matters is accustomed to shape her daily life, no matter whether it involves her own temporal happiness or that of those she holds dearer than her own existence, in accordance with her earnest interpretation of the divine will,

would not hesitate to pursue the course we have indicated as wrong. Not only will she do this in simple ignorance; she will do it in spite of all the moral and hygienic arguments that can be brought to bear upon her. She seems, indeed, impenetrable to reason in this regard—not deliberately sinful, but morally obtuse. Too often, to be sure, the considerations brought to her notice are wholly hygienic, and not at all moral, so that to her the matter is a mere balancing of a greater against a lesser physical ill—and for this we can not blame her. We repeat, she does not sin deliberately, but under a false moral illumination. Often, indeed, the true light breaks in upon her in her later life, and in anguish she bewails the acts which at the time of their commission she looked upon as allowable.

In spite of this tendency in human nature, we are firm in the conviction that the prevention of conception will ultimately come to be regarded as nothing more nor less than criminal abortion *in posse*. That there should be any sharp distinction between the destruction of an unborn child and the prevention of that child's existence is indeed strange. That it will soon be generally looked upon as strange we can not doubt. The Church of Rome, as our readers are doubtless aware, has never ceased to teach the sinfulness of sacrificing *fœtal* life, no matter what the pretext; and we would point to the increasing importance that year by year is attached to the question, Is craniotomy ever justifiable? The sanctity of *fœtal* life is continually urging itself more and more upon the attention of reflecting persons. From the destruction of life to the prevention of life is but a step.

There are indications that the time is not remote when the view we have held up will be accepted. Already it seems to have dawned upon the legislative mind, for quite lately one Hale, whose disastrous career in West Virginia we chronicle in another column, has got into the clutches of the law in Ohio for advertising a nostrum purporting to be a preventive of the continuance of gestation. One step more would make a law to punish attempts at preventing conception.

CO-OPERATION IN MEDICAL TEACHING.

THE supreme height from which a full-fledged professor is wont to look down upon his subordinates is proverbial. For what were the latter created, if not to eat crumbs in meek thankfulness? Any idea of reciprocity is seldom if ever entertained. The professor is making the assistant.

Such a state of mind is very natural, we concede; that it is altogether warranted by the actual facts is as far from the truth as could be imagined. It is not unknown to the present writer that a famous clinic has depended for its material upon a dispensary appointment held by one of the assistants. In the great majority of cases, indeed, the practical success of a clinic depends largely upon the efficient co-operation and the hearty good-will of the subordinates.

That such considerations are generally overlooked bears additional testimony to the astuteness of the faculty of the New York Polytechnic in making a *fœtal* dissection a *prima* importance of its assistant clinical staff by making them a *prima*

dinner. It is not that we do not give the faculty in question credit for a higher impulse than that of astuteness; we really believe that they are most cordial in their tribute to the efficiency and importance of their coadjutors. For our present purpose, however, we prefer to call attention to the aspect of the matter that we have indicated.

The Polyclinic has certainly been well managed. It will not do to invoke the latent demand for the clinical instruction of graduates as the sole explanation of its successful career. In this latter half of the nineteenth century, and in this city of New York, pigs do not roam the streets already roasted, crying, "Come, eat me!" Management is necessary.

If, in the first year of its existence, the faculty of the Polyclinic has opened its eyes to the prime need of drawing its clinical assistants by the closest bonds to its aid, surely the suspicion may be entertained that the older institutions might profit by the example. The material tender of a dinner is not what we conceive to be the bond that is to strengthen the solidarity of the various gentlemen composing the working force of the Polyclinic; it is rather the underlying recognition of a principle—one that will reach deeper than might be suspected—that will clinch the interest and the pride of the clinical staff in the institution that thus shows them its appreciation. We trust that the example will not be lost upon other collegiate organizations.

MINOR PARAGRAPHS.

A LEGAL QUESTION ABOUT CEMETERIES.

The right of the trustees of a cemetery to remove the bodies of persons interred therein, against the will of their relatives, is a matter of great public interest, and a recent decision by Judge Barrett in a case brought before the Supreme Court of this city has attracted considerable attention. The facts were as follows: The trustees of St. Patrick's Cathedral had been contemplating for some time the removal of bodies from the cemetery at the corner of Twelfth Street and First Avenue, in this city, for the purpose of selling the ground for business purposes, and were about proceeding to do so when a person, whose brother and two sisters had been buried in the cemetery between 1835 and 1842, obtained a preliminary injunction, alleging the setting apart of the ground for cemetery purposes and the payment of certain fees for interment, which, it was maintained, gave him a pecuniary interest in the matter.

The question of the authority of the Pope of Rome over church property in this country and various other matters were brought in, but the main point involved, upon the argument for an injunction against the removal of the bodies, was the extent of the powers of trustees to dispose of cemetery property. Judge Barrett held that there could be no injunction, as the trustees had the power to sell subject to the provisions of the law of 1878, and that the payment of dues or fees for interment did not give a person a right to prevent the removal of the bodies. The fact of sepulture does not necessarily render a cemetery for ever sacred to such uses, but, in case the property is sold for secular purposes, bodies can be removed and deposited in a new place of sepulture.

The law of 1878 is quite explicit on the subject, and provides that three fourths of the pew-holders of any church can legally determine the question of removal, if notice of a meeting is given two weeks in advance, and also published in a daily pa-

per. The decision of such a meeting must be properly certified, acknowledged in a manner similar to a deed, and recorded in the office of the register or clerk of the county where the cemetery is situated. When this is done, the trustees of the church can arrange for the removal of the bodies, and there can be no interference with them by the friends of deceased persons. There is great diversity in the way cemetery property has been set apart for burial purposes, and this decision does not probably apply to any cemeteries organized like Greenwood or Woodlawn.

THE NEW YORK POLYCLINIC.

THE remarkable success which has attended the first year's work of the New York Polyclinic was brought strikingly to the attention of those who had the pleasure of meeting the faculty of the institution last Saturday night, the occasion being a dinner given by them in honor of the assistant clinical staff. It appeared by the report of the secretary, Dr. John A. Wyeth, that during the year over five thousand patients had attended the clinics, and ninety-three had been visited at their homes, three hundred and eighty-two visits being made. One thousand and ninety-one prescriptions were dispensed. One hundred and sixty-one graduates in medicine attended the courses of instruction, coming from many different States and from several foreign countries.

On the occasion to which we refer, the president of the faculty, Dr. James R. Leaming, occupied the chair. Remarks were made by the Rev. Dr. Armitage in behalf of the board of directors, and by Mr. Charles Coudert, the president of the dispensary connected with the institution. The toast to the Medical Press was responded to by Dr. W. M. Carpenter, of the "Medical Record," and by the editor of this journal. Dr. Paul F. Mundé spoke in behalf of the dinner committee, closing with proposing the health of Dr. Wyeth, who responded briefly, after which Dr. R. C. M. Page, Dr. C. M. Cauldwell, and Dr. A. M. Jacobus, representing the assistant clinical staff, expressed the appreciation by their corps of the compliment tendered them by the faculty.

AN UNQUALIFIED PRACTITIONER'S EXPERIENCE IN WEST VIRGINIA.

WE are informed that one "Dr." Hale, professing to be a graduate of the University of Edinburgh, lately made his appearance in Wheeling, W. Va., where he offered credentials that the State Board of Health very properly declined to recognize, including a statement that his diploma had been indorsed by the United States Medical College, an institution recently declared illegal by our courts. It seems that Hale is the promoter of a periodical styled "Health and Home," published in Port Chester, N. Y., in which he bids for the degraded patronage of those who wish to avoid becoming parents, and openly argues in favor of the justifiability of feticide. The energy of the West Virginia Board of Health proved too much for "Dr." Hale, and we are told that he left Wheeling just in time to escape arrest. The officers of the board deserve the gratitude of their State and the commendation of all conscientious citizens for their summary suppression of Hale's infamous scheme.

THE QUESTION OF TESTAMENTARY CAPACITY.

THE frequency with which contests are made over the wills of deceased persons and the expense and uncertainty attending such suits have long been evils which were exceedingly apparent but hard to remedy. An important step was taken in this State to check the increase of such litigation when the Surrogate

decided, not very long since, not to allow the costs of the unsuccessful party in a will contest to be paid out of the estate, as had been the custom before that time. Another step in the same direction has just been taken in Michigan, and the success of the plan will be awaited with much interest. A law was recently passed in the Michigan Legislature allowing a person to make his will, and then during his lifetime petition the probate court for citations to all his heirs, and such other persons as he deemed necessary to attend an examination into his sanity and testamentary capacity. If it shall appear that the person was fully competent to make a will, a decree to that effect shall be made, and the question of incapacity can not be raised again, except upon appeal from the decree. If the testator subsequently becomes insane, and dies in that condition, his will, nevertheless, can not be questioned on this ground. The contents of the will are not to be made known until the death of the testator.

THE AMERICAN SURGICAL ASSOCIATION AND THE CODE CONTROVERSY.

The following is a copy of a letter recently received by Professor Alfred C. Post, of New York:

"AMERICAN SURGICAL ASSOCIATION,

"SECRETARY'S OFFICE,

"RICHMOND, IND., June 16, 1883.

"ALFRED C. POST, M. D.,

"DEAR SIR:

"At a meeting of the American Surgical Association, held in Cincinnati, O., June 2, 1883, the following resolution was adopted:

"Resolved, That the secretary be instructed to address a communication to each Fellow, active or honorary, who is alleged to have violated the code of ethics adopted by the American Surgical Society [sic] (see Art. IX of Constitution), and request him to withdraw from this body if the allegation be true."

"This communication is therefore addressed to you because your name appears on a printed list of gentlemen, in which it is stated you are 'opposed to the present code of ethics of the American Medical Association.'

"Very respectfully, etc.,

"J. R. WEIST, Secretary,

"A. S. A."

It appears, then, that the association construes an attitude of opposition to the code as a violation thereof.

THE NEW YORK CODE IN WEST PHILADELPHIA.

So recently as the 7th of May, the West Philadelphia Medical Society took the trouble to pass resolutions which the "Philadelphia Medical Times" characterizes as "strongly condemnatory of the action of 'certain mercenary men,' in New York and elsewhere, to overthrow the present code of ethics of the American Medical Association."

THE PREHISTORIC MAN.

It is said that in some recent mining operations in the Department of Pas-de-Calais, in France, a cavern was opened containing five fossil human bodies—a man, two women, and two children. The man's body measured 10-7-277 feet in length, and that of the taller of the two women 7-5-38 feet. There were also debris of arms and utensils of petrified wood and of stone, and numerous fragments of mammals and fishes. A second subterranean chamber contained eleven human bodies of large dimensions, several animals, and a great variety of objects, including precious stones. On the walls there were designs representing combats between men and gigantic animals. A

third chamber, still larger, seemed to be empty, but it could not be entered, on account of being filled with carbonic-acid gas.

A PHYSICIAN COMPELLED TO TESTIFY AS AN EXPERT.

Dr. S. T. Brooks, of St. Johnsbury, having made a post-mortem examination of the body of a murdered man, was recently called upon at the trial to testify as to the cause of death. He refused to testify, on the ground that he could not be compelled to give testimony as an expert without remuneration. Thereupon the judge committed the doctor to jail for contempt, but after a few hours' confinement he testified and was released. The other physicians who were present at the autopsy answered that they had formed no opinion as to the cause of death, thus avoiding a collision with the court.

A PROPOSITION TO ABOLISH THE OFFICE OF CORONER IN RHODE ISLAND.

At the recent annual meeting of the Rhode Island State Medical Society a communication was received from the Newport Medical Association, inclosing a draft of a bill providing for the abolition of the office of coroner, the duties of that office to devolve upon a body of medical examiners, to be appointed from the various counties, after the manner of the plan now followed in Massachusetts. Dr. Ariel Ballou, of Woonsocket, Dr. Samuel W. Francis, of Newport, and Dr. James H. Eldredge, of East Greenwich, were appointed a committee to report upon the matter at the next meeting.

"INDUCEMENTS" FOR THE ESTABLISHMENT OF A LUNATIC ASYLUM.

A BOARD of commissioners being charged with the duty, among others, of choosing a locality for a new State lunatic asylum in Indiana, it is said that they have addressed communications to various counties in the eastern part of the State, asking what "inducements," in the way of pecuniary contributions toward defraying the expense of building the asylum, they were willing to make. It is much to the credit of Fayette County that, as we learn, its people declined to enter into any such competition.

NEWS ITEMS.

THE JOHNS HOPKINS MEDICAL SCHOOL.—According to the Baltimore "Sun," it is probable that the medical department of the Johns Hopkins University will be opened about the 1st of October. Two of the university professors, Dr. Remsen and Dr. Martin, have been assigned, respectively, to the chairs of chemistry and physiology, and Dr. Billings, of the army, has been invited to become the professor of hygiene.

THE RHODE ISLAND MEDICAL SOCIETY.—At the recently second annual meeting, held on Thursday of last week, the following gentlemen were elected officers: President, Dr. Job Kenyon; first vice-president, Dr. Oliver C. Wiggin; second vice-president, Dr. Horace G. Miller; secretary, Dr. George C. Hensley; treasurer, Dr. C. H. Townsend. Members of the board of censors, Dr. Ariel Ballou, Dr. Otis Bullock, Dr. J. H. Eldredge, Dr. George P. Baker, Dr. J. W. C. Ely, Dr. Lloyd Morton, Dr. S. S. Keene, and Dr. Benjamin Greene.

A NEW STATE MEDICAL SOCIETY.—"Our Medical Journal" formally announces the project of a new medical society for the State of New York. There has been some talk lately been heard in this city for some months past, its promoters being those who can not reconcile themselves to the stand taken by the present State society in the matter of ethics.

SANITATION IN CINCINNATI.—By the failure of one of the courts to appoint a health commissioner, Cincinnati is now practically destitute of a sanitary department in its city government—a state of things which the facts about a recent outbreak of small-pox ought to bring to a speedy close.

YELLOW FEVER AT VERA CRUZ.—Reports from Vera Cruz to the close of last week represent that yellow fever was raging there, especially among the American and European residents. Ten deaths from the disease are said to have occurred in the hospital in one day, and about a thousand during the preceding two months.

AN HONORARY DEGREE.—The University of the City of New York has conferred the degree of doctor of laws on Professor Alfred L. Loomis, of the Medical Department.

THE STATE ASYLUM FOR IDIOTS.—The position of superintendent of the New York State Asylum for Idiots at Syracuse, to succeed the late Dr. Wilbur, is understood to have been offered to Dr. G. A. Doren, of Columbus, Ohio.

OBITUARY NOTES.

MORITZ MICHAELIS, M. D.—Dr. Moritz Michaelis, a native of Germany, and a practitioner in New York since the year 1840, died on Saturday, the 23d inst., in the seventy-second year of his age. Dr. Michaelis received the degree of doctor in medicine from the University of Berlin in 1835. It is said that for forty years he gave his services gratuitously to one of the Hebrew charitable societies.

Proceedings of Societies.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Meeting of March 1, 1883.

SEWER GAS, AND ITS ALLEGED CAUSATION OF TYPHOID FEVER.—Dr. GEORGE HAMILTON read the following paper:

The subject of the paper now to be presented is essentially similar to one read by the writer before the college in 1879, and reference to that paper will, from time to time, be made in regard to certain facts and statements therein contained. The opinion that sewer gas was, and continues to be, the principal cause of typhoid fever, and that all other causes combined are unequal to this single agent in the production of this disease, was opposed in that paper, as it will be in this. The views presented by Professor Frank Hastings Hamilton, of New York, in a paper on "Sewer Gas," published in the "Popular Science Monthly" for November, 1882, are essentially those accepted by an immense majority, either in or out of the profession; and, on the other hand, they are either rejected, or not accepted, as a rule, by practitioners and writers who have had the most frequent and abundant opportunities for observing the origin, development, and progress of the disease. The important question then involved in this subject can not be determined by mere numbers, but by an appeal to facts, not conjectural, because theoretical, but to such as are unrefuted, because insusceptible of refutation. The great and increasing importance, in a sanitary point of view, of several questions connected with this subject, may be regarded sufficient to justify the expression of opinions in opposition to those entertained by one so deservedly eminent in the profession as the author of the paper on sewer gas.

In support of the sewer-gas theory, Professor Hamilton declares "that the experience of every medical man, and of almost every intelligent citizen, is in accord." From an assertion in regard to medical men so sweeping as this, the writer cheerfully appeals to the page of medical history on this point; and the citizen must surely enjoy a rare degree of intelligence if he be capable of solving a problem in medicine that still remains *sub judice*. That the people in general have adopted the sewer-gas theory is beyond question; and the reasons for this are obvious. The efforts to gain over the public mind to this view have been, and continue to be, incessant, and these efforts have, in great measure, been made by physicians of enthusiastic temperament, but who, unfortunately, have had but limited opportunities to obtain a personal, practical knowledge of this subject. But, what is still more important, mankind are in general strongly disposed to accept as true that which promises pleasure, profit, and more especially health, exemption from disease, and longevity. The latter have been freely promised, provided that the sewers, and the house connections therewith, be properly constructed and kept in good condition; the filth in the streets, and every other place where it is apt to be found, be carefully removed, and disinfectants properly applied. In this way the stamping out of typhoid fever, scarlet fever, and diphtheria was confidently predicted. Here, then, was the true balm of Gilead presented to view, and is it surprising that almost every one, even the incredulous, should banish the dread that had so long held them in doubt and apprehension, and turn with wistful and confiding looks toward, and gladly accept, the proffered boon; when, too, all this was to be had by the mere expenditure of the requisite money for a certain amount of mechanical and other labor?

A most discouraging thing in this connection is found in the assertion, by Professor Hamilton and others, that, even when no sewer gas or offensive odor can be perceived, the gas, with its fatal germs, may yet pervade the residence of an occupant, while he is ignorant of any method of finding out whether or not such germs infest his home. This asserted fact is, perhaps, the key-note to the proposition, that all the ordinary or extraordinary and costly appliances now in use, and generally regarded, when kept in order, as capable of excluding sewer gas from dwellings, should be thrown aside, and that other apparatus should be erected in a detached structure, outside of the mansion. This proposition, emanating from a few sanitary engineers, is well-nigh impracticable. The plan has been tried in only a few cases, but not long enough to establish its supposed superiority. Colonel George B. Waring is quoted in the paper of Professor Hamilton as saying "that such plumbing work as is to be found in nine out of every ten houses, even in Fifth Avenue, is unsafe." What, then, must be the condition of ordinary houses, constituting the vast majority, in view of the limited pecuniary resources of their occupants? Sanitary engineer C. F. Wingate is quoted to this effect: that the constant demand for the doctor's services in so many houses in their normal bad state, and the fact that his services are no longer demanded when they have been put in sanitary condition, tells its own lesson. A lesson, to have value, the doctor forgets, must not be based upon assumed premises. From this quotation it does not appear that the apparatus was other than what is now in general use, but that it had "been put into sanitary condition," and in this he is in accord with a large majority of medical men and sanitarians. Dr. Barker, in his contribution to the paper on sewer gas, seems to deplore the fact "that of two young men, who suffered from typhoid fever, one died, and, upon examination, it was found that there was not a trap in the whole building!" But if the opinion of sanitarian Waring, and others who coincide with him, be correct, the mere existence of such

apparatus within the walls of a building serves, nine times out of ten, rather to increase than diminish the danger. The actual causation of disease, in general, is among the most obscure of medical problems; and in regard to the sickness of the Prince of Wales, cited by Professor Hamilton, and also that in the National Hotel at Washington, or that occurring during the Centennial Fair, medical opinions are not at all in accord. Professor Hamilton says "that plumbers suffer frequently"; but it has never yet been proved that they suffer more than others, although they are exposed to the action of sewer gas in its most concentrated form; and the reason why they do not suffer more, he informs us, is "that they are in most cases in the full vigor of adult life and health." The reason here assigned will, the writer is satisfied, surprise every physician who has had an extensive experience in typhoid fever, or who is familiar with the written history of this disease. From early manhood or womanhood until the thirty-fifth year is the admitted period of by far the largest number of attacks, and this holds good in several other acute maladies, notably in bilious remittent fever. In regard to this disease, the late Dr. Parrish, eminent as a citizen and a most experienced and practical physician, said to his class of students, "that if any of them became country practitioners they would find bilious remittent very prevalent and fatal as compared with the city"; and with emotion referred to his numerous consultations with country physicians within a radius of seven miles from Philadelphia, on either side of the Delaware, where he often witnessed the robust farmer, or his stalwart sons, sinking away into death, despite the efforts of the physicians. Now, that this form of disease is supplanted by the typhoid, a similar condition obtains, as may be seen, when the writer states that four cases of intestinal perforation occurred to him in the space of twelve months, while practicing in the country, thirty miles from Philadelphia. But more upon this point hereafter. Professor Hamilton also speaks of the "immunity which adults usually enjoy, and especially those who are most of the time away from home and in the open air."

On the contrary, in his country practice, the writer nearly always found that the young men who were away from their residence, at work in the fields, were more frequently attacked with typhoid fever than the females, who were generally engaged in domestic duties in or about the house; and if, as the sanitarians declare, "there is in the country houses, or the surroundings, something equivalent to sewer gas," why is it that the reverse as to sex should not be the case? Diphtheria is also said to be caused in great measure by sewer gas; why is it, then, that the most violent and fatal attacks of this malady occur in the country, sweeping off at times four, five, or six children in a single family, without a thought of sewer gas, while in cities, with sewer gas almost everywhere, the proportionate mortality is much less? Notwithstanding the testimony of Dr. Alfred Carpenter, of London, as quoted by the author of "Sewer Gas," to show the causation of scarlatina by this agent, here again such testimony is confronted by facts similar to those adduced in regard to diphtheria. It is only a few months since scarlet fever appeared in a town in Pennsylvania, noted for its cleanliness, and occasioned a proportionate degree of mortality unknown in Philadelphia. We now come to a singular and very important statement in the paper on "Sewer Gas," namely, "that in Asiatic cities, where modern improvements in plumbing are unknown, typhoid fever, diphtheria, and scarlet fever are seldom seen, while with us they have increased, as some declare, just in proportion to the extension of these improvements."

After this comes the admission of Dr. O. C. De Wolf, Commissioner of Health for Chicago, "that water-traps, as at present constructed, do not prevent the passage of disease germs

into our houses." Dr. Andrews is quoted by Professor Hamilton essentially as follows: "Canton is a city of bad smells; it has no water-closets or connection with sewers, and its *unsanitary* condition is unquestionable; yet there is rarely any typhoid fever or diphtheria." And he expresses his belief "that water-closets tend to propagate these diseases instead of preventing them." Professor Hamilton declares "that the several classes of professional experts seem to have lost confidence in each other, and are heard constantly charging one another with incapacity." The chemists apparently are not agreed, the plumbers are charged with incompetency, and they, in turn, regard the physicians as their "most wrong-headed customers," possessing only a "dangerous smattering" of knowledge upon this subject. An architect has complained "that men of his calling have been blackguarded, lectured, and blamed by eminent doctors for their supposed ignorance of matters of this sort"; and a sanitary engineer has said, publicly, "that there was probably only one architect in the city competent to execute the specifications for the plumbing of large houses," while a distinguished member of the National Board of Health said, publicly, "that he could count upon his five fingers all the sanitary engineers in this country in whom he could place any degree of confidence." If only the half of what has just been said be true, how embarrassing must be the condition of the public, and how greatly will be augmented the alarm, already so unnecessarily excited! and, in view of what has now been stated, may it not be thought that the motives thereto have not always been of a benevolent and purely unselfish character?

It is now time to confront the popular opinion that typhoid fever, diphtheria, and scarlet fever are caused by sewer gas, and that to a degree unequalled by all other alleged causes combined. In attempting to do this, such cases as the following will be completely ignored: Mr. A., on returning from his summer tour, perceived, distinctly, the smell of sewer gas in his house, and fell sick on the third day with typhoid fever. What can be said against sewer gas in this case? it may be asked. In answer, it may be said that while, by a bare possibility, the gas was the cause of the disease, the probabilities are all the other way. In the first place, the period of incubation is from eight to twelve days; in the second place, the writer's experience has convinced him that in not more than one house out of five has any smell or sign of sewer gas been detected, either before or during an attack of typhoid fever. And again, if the opinion lately advanced by a few of the most eminent authorities—that, as at present constructed and placed within the dwelling, the apparatus is incapable of excluding the gas—is correct, then, in such a city as Philadelphia or New York, many thousands more must be added to the tens of thousands of houses said long ago by the alarmists to be infected with sewer gas. In this connection it may further be stated that, if the dwellings of this city and those of New York are infected to the extent asserted, then the conclusion is inevitable that the mortality would be absolutely frightful, and yet in some weeks, in our city and in New York, with, taken together, about three millions of people, the deaths have been down to two, three, or four, while diphtheria, caused, as sanitarians and inexperienced physicians say, by the same sewer gas, has at this identical time occasioned, weekly, the death of about thirty or forty persons. In the third place, it is well known that many individuals, on returning from the country to their homes in the city, in a very few days, before the period of incubation has expired, have had attacks of typhoid fever, and such cases may fairly be regarded as having had their origin in the country.

Another instance of typhoid fever is this: A complaint was made to the Board of Health that a stagnant pond upon the outskirts of the city had already caused two persons to fall sick

with fever. The pond was, by order, filled up, the patients recovered, and no others were attacked! Could anything, many would ask, be clearer than the exciting cause of these attacks? That a vast majority would regard the cause assigned as the true one need not be doubted; but it is not to be forgotten that a large majority of people are by nature credulous, and, as a rule, the credulous are not logical, and the faith of such persons, as Goethe and Richter have said, is a matter of feeling, affection, aversion, rather than of reason, as the following example, in relation to that just quoted, may serve to illustrate. Into the family of a wealthy farmer, a few miles distant from the ill-conditioned pond alluded to, typhoid fever entered at about the same time as in the former case; several of the members were attacked, and, as in the former instance, all recovered. There was no stagnant pond here to complain of; on the contrary, the farm lay in a beautiful elevated section of the country, was in all respects a model farm, the agriculture, domestic and general economy exceptionally good; yet all this, as the writer had often seen in his rural practice, occurred without the agency of sewer gas or (apparently) any other one of the agents so commonly held responsible for these attacks.

The writer is well aware that the points maintained in opposition to the current views as to the origin of typhoid fever are not accepted by a very large proportion of medical men and sanitarians; but it should be remembered that, by the reports of the Board of Health of Philadelphia, there have been on an average weekly, for the last ten or twelve years, but seven to eight deaths; hence, it is evident that, with all the alarm in regard to typhoid fever, there has not been opportunity for one half of the regular physicians of this city to become fully acquainted with the disease, in its various forms and aspects. In every instance, however, when the writer has inquired of any one who had practiced extensively, both in town and country, the answer has been nearly always that the disease, when it appears in the country, is infinitely more prevalent and fatal than in the city, and that, as a rule, it was impossible to discover whence it originated. But on this point let us turn to an eminent authority—Trousseau, that great medical light of the nineteenth century. After speaking of the great difficulty of discovering the intimate causation of disease in general, and of the great advantages of the practitioner in rural districts in regard to this point, he declares "that the ordinary causes given in explanation of the origin of typhoid fever are trivial (*banal*), and deserve no serious consideration."

Trousseau did not rashly, as often happens, declare his opinions on this point. His opportunities for the study of typhoid fever in Paris were abundant, yet he was not satisfied with these, knowing, as he did, that the rural practitioner, having personal intercourse with nearly every family within a limited range, and consequently having superior advantages for observing the first outbreak and the progress of disease, would be most capable of arriving at a knowledge of its origin, whether from local or general agencies, or from contagion. To this source of information he often resorted, either by letter or personal interviews; and, ended as he was with an eloquence brilliant and comprehensive, a marvelous power of observation, and logical acumen, it is not strange that in life he was, and yet remains, in the first rank of philosophic medical authorities.

In illustration of the above statement, my own experience may here be alluded to. Leaving Philadelphia in the autumn of 1834, a location was chosen at the distance of thirty miles from the city, between Wilmington and Kennet Square, seven miles distant from either, and about eleven from West Chester. The surrounding country was hilly, abounding in springs of fine water. Bilious remittent and intermittent fevers prevailed at this time, and for a few years after, in Philadelphia, to an ex-

tent that has not since occurred. The remittent form only held possession of this rural section, and before the frost of November put an end to the disease, as it always did, the statement of Dr. Joseph Parrish in regard to its prevalence and fatality in the country was fully confirmed in my own experience. After five or six years, bilious remittent was supplanted by typhoid fever, and it would be inexcusable did the writer neglect to cite two or three instances of this malady, of marked importance in relation to its origin and development. A wealthy farmer had sent a son on business into Maryland, forty miles from his residence. After an absence of several weeks he was brought home affected with typhoid fever, and, in succession, the father, two other sons, two daughters, and a colored servant were attacked, all severely except the servant, the mother alone escaping the disease. An attendance lasting four months was required, and, although three of the patients were in great danger, all recovered. In another family of seven persons, four were prostrated, one, a young man of eighteen years, dying from perforation. In this instance, again, the disease did not originate on the premises. The mother, the first attacked, had been absent from home assisting to nurse a relative, at a distance of several miles from her own residence, to which she was brought unwell, and thus communicated the disease to the others. Many physicians, perhaps all professed sanitarians, are in the habit of expatiating upon the great and unnecessary prevalence of what they call filth diseases—typhoid fever, scarlet fever, and diphtheria—in large cities, and seem indisposed to turn their attention to the country until reminded, from time to time, of the ravages of these same diseases in rural sections, greatly exceeding, in proportionate number of cases, violence, and fatality, what is to be found in cities. Yet the sanitarian, or the inexperienced practitioner, fertile in expedients, soon discovers the sources of their origin in decomposed vegetable matter in cellars and elsewhere, or in water and milk contaminated by the requisite family out-house, while the attending physician, though upon the spot, can not, unless in exceptional cases, find any rational ground for these necessitated conjectures. But, in this connection, let us revert to the condition of agriculture and husbandry in regard to household, dairy, and stable economy half a century ago. At this period agricultural journals, or other works pertaining to those subjects, were scarcely known, while, for very many years past, they have been disseminated over the land, throwing a flood of light upon all that concerns agriculture and husbandry, the good effects of which are now visible on every side. It might here rationally be asked, What was the state of the country at the early period named, and was there not much more typhoid fever than has since occurred? On the contrary, typhoid fever, and also diphtheria, were almost unknown at that time, while bilious remittent, not generally regarded as a filth disease, prevailed, and so continued until about five years before the return of the writer to Philadelphia in 1845. As before intimated, a sharp frost or two would arrest the progress of bilious fever; not so in regard to typhoid; on the contrary, one of the worst invasions of the disease continued throughout the winter and early spring, and this peculiar and important feature finds its counterpart, not seldom, in this and other cities, where, independent of the agencies of warmth and moisture in promoting the decomposition of animal and vegetable matters, and evolution of gas, the disease has prevailed in an aggravated form.

In the writer's experience it did not often happen that either typhoid or remittent fever prevailed extensively in two consecutive years. In this respect it resembled dysentery, raging with a fatality this year unseen in the city, while during the following season very few cases would appear—the local conditions in either case presenting no perceptible change.

AMERICAN NEUROLOGICAL ASSOCIATION.*

(Concluded from page 692.)

Second Day—Thursday, June 21st.

The meeting was called to order by the president, Dr. ROBERT T. EDGES, of Boston.

ELECTION OF A NEW MEMBER.—Dr. RALPH L. PARSONS, of Sing Sing, N. Y., was elected a member of the association.

THE EXCRETION OF PHOSPHATES OR PHOSPHORIC ACID AS CONNECTED WITH MENTAL LABOR.—The President read a paper on this subject in which he referred to the generally accepted statement that mental labor increased the amount of phosphates in the urine. It was difficult to determine exactly what hard mental labor consisted in, each individual viewing the question from a personal standpoint. It might be considered that, when one felt himself to be putting forth special mental effort, although to another person the task might be quite easy, he was doing so in fact.

The President's conclusions in regard to the effect of mental exertion on the excretion of phosphorus had been drawn from experiments upon himself, which consisted in measurements of the quantity of phosphates in the urine shortly after, and in some instances several hours after, lecturing and being engaged in other mental labor, and also after a period of leisure. To avoid liability to error, in a few cases the urine secreted during the same night was also examined. In nearly every instance the amount of phosphorus was less in the urine passed after a period of mental labor than in that passed after a period of mental repose. This was due, perhaps, to the fact that the quantity of urine secreted was also found to be less. His experiments had not determined that the amount of phosphorus metamorphosis within the brain was not increased during mental labor, but they had shown that the increase, if any, was not sufficient to be apparent when measured with the entire quantity arising from changes taking place in all the tissues of the body; no more so, indeed, than would a slight rain at the head of the Mississippi become apparent at its mouth by the rise in its waters.

Dr. MILES, of Baltimore, asked whether it was known that phosphorus existed in the nerve cells themselves, the part of the nervous structure which was active during mental labor, whether it was not in fact confined to the substance of Schwann, or the inactive part. The opinion of those present seemed generally to be that the oft quoted statement that mental labor increased the amount of phosphorus in the urine was fanciful, and not supported by experimental observation.

The paper was also discussed by Dr. PUTNAM, of Boston; Dr. MORTON, of New York; and Dr. JEWELL, of Chicago.

Dr. S. G. WEBBER, of Boston, reported some CASES OF LOCOMOTOR ATAXIA WITH UNUSUAL SYMPTOMS AND MARKED REMISSIONS IN THEIR COURSE.—The first case was one in which there was severe gastric disturbance, consisting in flatulence attended by extreme pain. The second was interesting from restriction of the respiration. The third was characterized by diabetes.

* In our report of the first day's proceedings, in the last number of the journal, the following corrections should be made: The case mentioned by Dr. Weber (p. 692, first column, third line from the bottom) was one of *leptocystodermatitis*, not "polysomnitis." In Dr. Sprague's remarks (p. 692, second column), instead of "which nothing could be more remote than the larval enlargement of the cord from the reflex area and the speech centers, unless it were the larva from the olfactory bulb," read: "Which nothing could be more remote than the larval enlargement of the cord and the enlargement of the speech centers, unless it were the larva from the olfactory bulb." —REPORTER.

The fourth was marked by diabetes with urinary sugar being found. In the remaining cases the urinary sugar was not lost or had returned. In the last three cases of the eight reported, the patients seemed to have been cured of the locomotor ataxia. The prognosis was more favorable in the cases in which the symptoms developed rapidly.

The paper was discussed by Dr. MORTON and Dr. W. A. HAMMOND, of New York.

Dr. R. W. AMMON, of New York, presented a CASE OF TETANOID PARAPLEGIA OCCURRING IN A CHILD, the tetanoid manifestations being preceded by a train of symptoms indicating subacute hydrocephalus. He asked whether the central trouble might not account for the tetanoid symptoms by causing descending changes in the spinal cord.

Dr. AMMON also presented a Case of *Paralysis Agitans* (PARKINSON'S DISEASE), the peculiarity consisting in the entire absence of tremor; all the other symptoms of paralysis agitans were present.

The paper was discussed by Dr. MORTON and Dr. DANA, of New York; and Dr. PUTNAM, of Boston.

Dr. V. P. GIBNEY, of New York, presented a patient in illustration of PROGRESSIVE MUSCULAR ATROPHY with marked fibrillary twitchings, and also a patient with fibrillary twitchings following a gunshot wound.

AN APPARATUS FOR TREATING SPASTIC PARALYSIS was the title of a paper read by Dr. W. J. MORTON, of New York. While writer's cramp was not a fatal disease, there were few diseases of the nervous system less curable and more disastrous to the patient's occupation. Better results had been obtained, in his experience, by treating the muscles partly by the use of any form of electricity. Wolff's method of treatment by active and passive exercise of the affected muscles had not proved so successful at the hands of others. He thought the benefit derived by Wolff's method was due to stretching of the muscles, but was of the opinion that it was no more permanent than when the same method was adopted in contractures due to central lesions. Reference was made to the treatment devised by Nussbaum. This method was more simply carried out in the following manner: A thimble was worn on the index finger, consisting of very light elastic metal, split from end to end, clasp the finger entirely; a light elastic rubber band was slipped over the thumb and index, clasp the thumb and index together, and abduction; to the end of the thimble the pen was attached. The patient thus wrote by movements at the shoulder, those of flexion and abduction being restrained at the fingers.

The paper was discussed by Dr. PUTNAM, Dr. WEBBER, Dr. WALTON, and Dr. DANA.

THE INSANE OF STAFF AND THEIR ATTENDANTS, a communication from Dr. E. C. SEGIN, was read by title.

July 1st—Friday.

A CASE OF LOCOMOTOR ATAXIA—The case was reported by Dr. G. M. HAMMOND, of New York. The patient was a young man, who, about ten years ago, came under the care of Dr. Anderson, with a lesion of the glans penis. It was not known whether the lesion was a chancre or a chancre. Secondary symptoms did not manifest themselves. The patient had five children perfectly healthy. He had been a drinker for several years, and in the winter of 1872-73 he had an attack of delirium tremens. Following the attack of delirium tremens the symptoms of ataxia were fully developed; but the patient said that, for about six months before, he had felt sharp pains down the legs, and a little difficulty in walking. There were now all the regular symptoms of locomotor ataxia: inability to stand without support, with the eyes closed or open; ataxic walk; incontinence; loss of sensation; and other symptoms.

were similarly affected. There was no paralysis of the bladder, but there were partial loss of sight and defective memory. Dr. Anderson administered iodide of potassium and corrosive sublimate. The patient was sent to Dr. Hammond, who applied the actual cautery to the spine, and faradaic and galvanic electricity. From this time the patient began to improve, and at the present time was apparently in normal health; he walked perfectly, could jump on to a car while in motion, and could stand with the eyes closed; tickling of the feet was felt distinctly, and tendon reflex had partially returned. This was the only case in which Dr. Hammond had known the tendon reflex to return even partially.

Dr. W. A. HAMMOND said that this might be the only case on record in which tendon reflex had returned, but during the past ten months he had treated a similar case in which the tendon reflex had markedly returned, especially in one knee, and most of the ataxic symptoms had disappeared.

Dr. PUTNAM said that one or more cases had been reported by Baerker in which tendon reflex had returned. Schuster had reported a case, also seen by Erb, in which the patient recovered from the ataxic symptoms, and in which, after death, characteristic lesions of locomotor ataxia were found.

The paper was further discussed by Dr. MILLS.

NUTRITIVE ALTERATION OF THE HAND FROM THE PRESSURE OF A DISLOCATED HUMERUS IN THE AXILLA.—Dr. F. T. MILES, of Baltimore, read a paper in which he gave the history of the case of a man fifty years of age who, two years before, fell and injured his shoulder, and afterward suffered extreme pain down the corresponding arm to the fingers, which he was unable to move. He was confined to the house during five months. The severest pain was located in the shoulder. The surgeon then found an unreduced luxation of the humerus into the axilla. There was great deformity of the ring and little fingers, and the skin was pale and presented a glazed appearance. The fingers could be moved but slightly, and movement at the wrist joint was limited. Touching a finger caused the arm to jerk away in a peculiar manner, but not from pain. The author believed that physicians were inclined to stick too close to custom in always looking for a particular set of symptoms, such as pain, thickened nerve, etc., in any supposed case of neuritis; that the foregoing case, and others which he narrated, illustrated the fact that there might be other changes present, due to an affection of the sensory, motor, and trophic nerves, than the subjective symptoms referred to; and that the symptoms varied greatly in different cases.

THE BRAIN OF THE CAT LACKING THE CALLOSUM.—Dr. BURT G. WILDER, of Ithaca, N. Y., presented photographs, together with a specimen, which had been removed from a cat that had shown no peculiarity, so far as was known in 1879. He would some time in the future dissect the specimen for more minute study. In reply to a question by Dr. Morton, he said that what effect absence, or partial absence, of the callosum in man would have upon his character had not been determined exactly by observation. In one case it was only noted that the man, a soldier, had been quarrelsome and dirty.

The paper was discussed by Dr. W. A. HAMMOND, Dr. PUTNAM, Dr. MORTON, and Dr. MILES.

ON THE ALLEGED HOMOLOGY OF THE CARNIVORAL FISSURA CRUCIATA WITH THE PRIMATIAL FISSURA CENTRALIS.—This was the title of another paper read by Dr. WILDER. The author quoted various writers, showing that the terms correspondence, analogy, and homology in relation to the cerebral fissures and convolutions were not properly distinguished from each other; and that a difference of opinion existed as to what fissures and convolutions of the brain in the cat, in the monkey, and in man should be considered homologous. Parts which might be con-

sidered apparently homologous from an anatomical point of view might not be so physiologically. It was important, first, to determine homologous parts in man and the monkey; and, second, in the cat and the seal, and after this we might hope to determine homologous parts in the more distantly related species, man and the cat.

Dr. BIRDSALL thought it would be difficult to say that parts apparently homologous anatomically were so physiologically.

Dr. W. A. HAMMOND said that the same cerebral lesion in two men would be followed by different physiological symptoms; injury to the third frontal convolution in one individual would cause loss of speech; in another it did not produce any such result. It would readily be seen, therefore, what difficulties would attend attempts to determine homologous cerebral parts in man and the carnivora.

The paper was further discussed by Dr. MILLS and the author.

ON THE TREATMENT OF MIGRAINE was the title of a paper read by Dr. W. J. MORTON, of New York. The object of the paper was to call attention to a more systematic treatment of the affection than was generally adopted. Two types of migraine were described, the one spastic and the other paralytic, depending, respectively, upon contraction or dilatation of the blood-vessels, through the influence of the vaso-motor nerves. In the treatment of the spastic form, the bromides were specially effective, the bromide of sodium in general being preferred, because so much better borne than the potassium salt, as determined by the experiments of Ringer. Sixty grains administered at the beginning of an attack, and, if necessary, repeated in an hour, would usually abort the attack. Nitrite of amyl and nitro-glycerin were often very beneficial, the latter being preferable because more permanent in its action. It should be given after meals, in order to avoid uncertain effects due to possible decomposition in an alkaline stomach. In the paralytic type strychnine was recommended, but ergot was the most useful in aborting the attack, and causing contraction of the vessels. The medicine should be continued afterward. It might be given by the mouth or hypodermically. Cauterization and methodical applications of electricity were also beneficial.

Dr. W. A. HAMMOND had found strychnine even more valuable than ergot. He accepted Dr. Morton's division into the spastic and paralytic types. He asked Dr. Morton how he would treat a case in which there was the spastic variety upon one side and the paralytic upon the other, of which he had seen two examples, which he had been unable to treat successfully.

Dr. J. L. CORNING, of New York, referred to treatment by compression of the carotids.

Dr. WILDER had found compression of the carotids a successful method of checking the pain of migraine in his own case. He mentioned the fact that he once had toothache in which severe pain occurred only with every other pulsation.

Dr. HAMMOND thought this probably explained by the fact that the alternate pulsations were the stronger.

Dr. C. L. DANA, of New York, did not believe that it was always possible to divide migraine into the two classes of cases mentioned, or that the exact nature of the case could always be determined. He had given decided benefit by frequently repeated small doses of cannabis indica.

The PRESIDENT agreed with the first statement made by Dr. Dana, and said that he was unable to determine which form, the spastic or the paralytic, he had suffered from for a number of years. The attacks were aborted by a two-drachm dose of bromide of potassium taken on going to bed. Caffeine was beneficial in certain forms of headache.

The paper was also discussed by Dr. PUTNAM and Dr. MILLS. Dr. W. R. BIRDSALL, of New York, made some remarks upon

the RELATION OF SYPHILIS TO LOCOMOTOR ATAXIA, quoting the tables of several authors, in which, out of a total of 525 cases of locomotor ataxia, there was a history of syphilis in 225 cases, or 43 per cent. His own statistics, taken from the records of Dr. Seguin's clinic at the College of Physicians and Surgeons, and his own clinic and that of Dr. Seguin at the Manhattan Eye and Ear Hospital, showed a positive history of syphilis in but four cases out of forty-two. He therefore could not believe with Erb that locomotor ataxia always followed syphilitic disease. Dr. Birdsall also presented an electrical instrument.

Dr. MILLS said that his experience had certainly been very strongly opposed to that of Erb, which went to show an inviolable relation of locomotor ataxia to syphilis.

GALVANIZATION OF THE BRAIN AND ITS VALUE IN THE TREATMENT OF CHOREA.—Dr. C. L. DANA, of New York, read a paper with this title. The effects of galvanization of the brain were classed as subjective and objective. The author then described the subjective and the objective symptoms produced by galvanization of the brain of man and of animals, in health and in disease. It was concluded that anodal electricity applied to the brain had a sedative action, retarded the circulation, and produced a beneficial result in chorea. Eight patients, and others of whose cases he had not kept notes, had been cured by the use of the anodal pole, alone or in conjunction with the use of arsenic. At first the improvement in the symptoms seemed to pass away, as felt by the patient, after twenty-four hours. When continued, a cure was effected on an average within twenty-five days, whereas with arsenic alone the average duration in thirty cases had been six weeks. He believed that the direct effects of the current were obtained. His conclusions as to the treatment of chorea in this manner were supported by Berger and Erb.

Dr. CORNING had obtained beneficial results in chorea by the use of galvanism in connection with arsenic, and also galvanism and cold in connection with arsenic. The latter treatment—that of galvanism with cold—was particularly satisfactory in the treatment of headache.

Dr. MILLS thought the action of the current was reflex, not direct, as used by Dr. Dana.

Dr. WEBER thought that, if the beneficial results were not obtained except when arsenic was given at the same time that galvanism was employed, they could very properly be attributed to the action of the arsenic.

The paper was further discussed by Dr. BIRDSALL, the Author, and Dr. MORTON, who alluded to some uncertainties attending the use of anodal electricity, as had been recently pointed out. He suggested the possibility of taking advantage of the anesthetic state produced in some patients by the electrical current for the performance of surgical operations.

ON THE REMOVAL AND PRESERVATION OF THE HUMAN BRAIN.—Dr. WILDER read a paper in which he spoke of the importance of preserving the brain without the least injury to its parts, and in a perfect state. The skull of the new-born, and of young cats and dogs, could be removed by side-cutting nippers. In older calvaria, before the circular incision was quite completed by the saw, a longitudinal division should be made a little to one side of the line of the longitudinal fissure, and the smaller section of the calvaria be removed; and, before proceeding to remove the larger section, the dura mater should be loosened in the median line by the bent point of a shoe-maker's knife. During removal of the brain from the base of the skull, it should be supported in strong brine. To preserve the brain perfectly, alcohol, in a weak dilution at first, should be passed through the carotids constantly for several days, by siphon pressure. The ventricles of the brain should be kept distended by frequent injections of diluted alcohol. It was un-

necessary to preserve the entire brain except for special purposes. He employed alcohol alone. That this agent was the best for histological specimens, he could not say. The method was specially of advantage to those making preparations for museums.

Dr. MILLS had found it of advantage in many instances to leave the dura mater attached to the calvaria.

Dr. E. C. SPITZKA, of New York, removed a posterior section of the calvaria, also including the posterior part of three or more of the cervical vertebrae. The brain could then be removed, dividing its attachments from behind forward. Alcohol was not a fit agent in which to preserve specimens for microscopical examination.

Dr. MILES described an instrument for retaining the head in any desired position during the removal of the calvaria.

Dr. WILDER then read a portion of a paper on SOME POINTS IN THE ANATOMY OF THE HUMAN BRAIN.

The remaining papers—one by Dr. LEONARD WEBER ON THE NEUROLOGIC QUERIES OF ARTHUR DUFFENHAGEN, read jointly by Dr. WALTON—were considered as having been read by title, and the association adjourned, to meet next year at a place and time to be determined upon by the Council.

NEW YORK MEDICAL AND SURGICAL SOCIETY.

A STATED meeting was held January 13, 1883, Dr. C. R. AGNEW Chairman for the evening.

ENDARTERITIS OBLITERANS. MEDIC PROGRESS AND DEATH FROM A SMALL CEREBRAL LESION.—Dr. FRANCIS DELAFIELD reported the following case: A man about thirty years of age had been in good health until the 11th of November, 1882. On the afternoon of that day he had a severe headache, which became worse, and in the evening he grew stupid, almost comatose. The condition of stupor continued, and on the next day there was complete motor paralysis of the left leg, arm, and side of the face; sensation remained. After two or three days the intelligence began slowly to return, and the patient's whole condition gradually improved, so that by the 16th of November he was able with assistance to walk about the house. On the 19th, however, he had a relapse, the mental stupor and motor paralysis began to return, and by the 30th of the month he was again completely comatose and paralyzed on the left side. Death took place on the 5th of January. At the autopsy the only lesions found were in the brain. A portion of the corpus striatum of the finger nail lay in the caudate nucleus of the corpus striatum on the right side, and another smaller one just below in the internal capsule. The large arteries at the base of the brain were the seat of obliterating arteritis. The arteries leading to the seat of the lesions could not be traced. The case was interesting in at least two respects: first, as being another example of the cases which of late seemed to occur somewhat frequently, a class in which cerebral symptoms were dependent, not upon embolism, but upon disease of the arteries; and, secondly, with regard to such serious results following a small cerebral lesion. It was difficult to understand how so small a destruction of brain tissue could cause not only motor paralysis, but also death. There was no other path to account for such a grave result than from the cerebral lesion. Such cases were so often met with that one could almost say the presence of an arterial death was worse in cerebral lesions of small size than in those of large size. It was true that in some cases temporary improvement in the mental and motor symptoms took place, but the latter soon returned and led to a fatal result in a brief time.

REPORT OF AN INTERESTING CASE OF THE LACERATION OF THE SPINAL CORD.—Dr. A. B. BAKER read the following case: A young woman sustained an injury while dancing and fell carrying her

fainting daughter to a bed. She was not conscious of any special strain at the time, but, on rising from bed several hours afterward, she found that she was quite lame in the right leg, and suffered some pain in the calf. This localized pain increased in severity during the day and night, and the leg became somewhat swollen. The pain then extended upward, reaching to about the origin of the sciatic nerve. When Dr. Ball saw the patient on the following day, he found a tumor as large as a hen's egg about three inches below the knee, at the junction of the inner with the posterior aspect of the leg. It was soft and very tender. On the posterior surface of the leg there was a spot of ecchymosis, of a yellowish color, of about the size of a twenty-five cent piece, which by the next day had extended down upon the foot. Dr. Ball supposed that the tumor was due to an extravasation of blood from a ruptured blood-vessel, probably an intra-muscular vein, and that the pain, which had increased in severity, was due to pressure of the tumor upon the nerves. The tumor was now growing smaller, but the patient was still confined to bed. She had not had gout or varicose veins.

LOW TEMPERATURE IN GENERAL TUBERCULOSIS.—Dr. H. F. WALKER narrated the history of a patient who died recently at Bellevue Hospital of general tuberculosis, the interesting point being that the elevation of temperature was only very slight throughout nearly the entire course of the disease. The patient was a man thirty-two years of age, who, for about three weeks previous to his admission, had suffered somewhat from a cough and from looseness of the bowels, which succeeded constipation. At the time of his admission, November 16, 1882, an examination of the chest revealed very slight dullness at the apices of the lungs and slight broncho-vesicular respiration; posteriorly there were signs of bronchial catarrh, and under the right clavicle there was a point of consolidation of about the size of an English walnut. The patient grew steadily weaker, the cough did not increase, but delirium developed which made it necessary to employ restraint. He died, in a state of coma, on the 26th of the month. Previous to the 21st the temperature had varied from 99° to 99.5° Fahr.; on the 21st it was 100°; on the 22d, 101.5°; on the 23d, 99°; on the 24th, 103°; on the 25th, in the morning, 98.5°; in the evening, 101.8°; on the 26th, the date of death, 103°. At the autopsy the lungs were found studded with small tubercles; there were also small spots of lobular pneumonia. The patient had been jaundiced during his illness; tubercles were found upon the capsule of the liver, and the capsule of the kidneys, the pericardium, and the tunica vaginalis were the seat of tuberculous deposits; none, however, were discovered on the membranes of the brain. The intestines were free from ulceration. During the patient's life, Dr. Walker had hesitated to make a diagnosis of general tuberculosis, on account of the almost uniformly low temperature.

Dr. DELAFIELD thought it was not unusual for cases of general tuberculosis to run their course with a temperature varying between 99° and 103° Fahr., sometimes even lower. He recalled one case in which the temperature at no time rose above 99.5°. He believed that the majority of cases in this city showed a low temperature, and when it rose to 106° or 107° it was an exception. The height of the temperature, however, varied in different places, according to statistics. In reply to a question by Dr. McCready, Dr. Delafield said he did not think that the rapidity of the course of the disease had any bearing upon this point. With regard to a question by Dr. Agnew, whether any relationship seemed to exist between the tuberculous deposit upon the membranes of the heart and the condition of the circulation, the tissue change and the temperature, Dr. Delafield replied in the negative.

INTESTINAL STRANGULATION.—Dr. DELAFIELD referred to the

case of a young man who recently died in Bellevue Hospital of intestinal strangulation. On the evening preceding the fatal illness the patient had gone to bed in good health. He awoke at three o'clock suffering from agonizing pain in the abdomen, and was brought to the hospital in an ambulance early the same morning, still suffering from exceedingly intense pain, and being apparently in a moribund condition. The abdomen was very tympanitic. Morphine was administered in considerable quantities, but the patient died within twenty-four hours from the onset of the attack. At the autopsy a hole, half an inch in diameter, was found in the mesentery, through which about six feet of the small intestine had passed and become completely strangulated.

A STATED meeting was held January 27, 1883, Dr. AUSTIN FLINT Chairman for the evening.

URINE OF LOW SPECIFIC GRAVITY CONTAINING SUGAR.—Dr. T. F. COCK said with reference to the question of urine of low specific gravity containing sugar, which had been raised at a former meeting of the society, that he had since looked over the notes of several hundred examinations of urine, made in his practice during the past three years, and had found that the lowest specific gravity of urine which contained sugar was 1.008, and the highest 1.044. There were several instances in which the specific gravity was 1.010, 1.014, or 1.015.

Dr. A. B. BALL remarked that he thought the question raised at the former meeting was not with regard to the possibility of urine of low specific gravity containing sugar; doubt was simply expressed whether urine of low specific gravity could contain sugar in large amount. In minute quantities sugar had been shown to be a normal ingredient of the urine.

Dr. AUSTIN FLINT asked whether any of the members had used bromide of potassium in the treatment of diabetes. A French physician, whose name he could not recall, had cured a number of cases with no other treatment than the administration of the bromide of potassium; hygienic restrictions were not imposed. Dr. Flint believed that he himself was the first to suggest the use of bromide of potassium in diabetes, having obtained marked benefit from its administration in a certain case about twenty years ago. It had not proved equally efficacious in other cases. Recently he had prescribed the drug in the case of a poor patient who was unable to carry out the dietetic treatment, but during the period that it was taken, which was two or three weeks, the amount of sugar in the urine increased. He had received a letter from a physician in Massachusetts who was suffering from diabetes, and who had done well on the dietetic treatment for several years; but his friends suggested that he should take bromide of potassium, and at the same time continue the dietetic treatment. He did so, and the amount of sugar in the urine, instead of being diminished, was increased, and other unpleasant effects followed. This physician knew of another similar case.

Dr. Flint mentioned a case in which diabetes had probably been present a considerable length of time, and the patient was put upon the use of the arsenite of bromide, about two drops three or four times a day. Under this treatment sugar had entirely disappeared from the urine. The dietetic treatment had first been tried, and with marked benefit, but the sugar had not entirely disappeared from the urine.

A SORE OF PECULIAR CHARACTERISTICS DEVELOPED ON THE BACK OF THE NECK.—Dr. T. M. MARKOE reported the following case: The patient was a man sixty years of age, of good habits, and in good health up to within a recent period, when, without any known cause, a sore, supposed to be a boil, developed on the back of the neck a little to one side. The center of the sore, instead of coming to a point, as it would have done

had it been an ordinary boil, became indurated, the induration involving the cutaneous, the areolar, and the fatty structure. The skin itself was perforated in a few spots by small holes. The surface was of a red, inflamed appearance, which gradually faded toward the periphery. Disintegration took place, beginning at the center, the tissue presenting a yellowish, custard-like appearance, and separating with difficulty. The sore continued to spread and to undergo this slow process of ulceration until an area was involved reaching to the back of the right shoulder and three inches to the left of the median line, up the back of the neck and head to the vertex, then down upon the side of the neck and forward to the median line and upon the clavicle. At a point near the vertex the tissues at the edges of the sore were unusually thick, causing a prominence beyond the level of the scalp. After some time the ulcerative process upon the fore part of the neck took on a more active state, dissecting the tissues as cleanly as if it had been done with a knife. The trachea and the line of the esophagus could be seen, remaining after separation of the overlying tissue. Hoarseness developed, and the patient died of some laryngeal complication about a month after the commencement of the disease. This was the second case of the kind which Dr. Markoe had seen, the first case having occurred in a man of about the same age, the disease following nearly the same course. In that case the process involved the entire side of the head and face, destroying the tissues completely. The thickening of the margins of the ulcer upon the head was so great that the diameter of the ulcer was absolutely greater than that of the head. The destructive process was slow, and the patient died of exhaustion about a month after the development of the sore.

GAUTHERIA IN RHEUMATISM.—Dr. Flint said that Dr. Alexander, one of the house physicians at Bellevue Hospital, furnished him the following statistics with regard to the use of gaultheria in that institution in cases of acute articular rheumatism. Of thirteen cases thus treated, of which the histories were given, one patient contracted pneumonia after the cure of the rheumatism, and died in the hospital; a second one remained in the hospital, at the expressed wish of the commissioners, some time after cure of the remaining eleven cases; the longest duration of the disease in any one case was fifteen days, and the shortest two days. The average length of time that the eleven patients remained in the hospital was a fraction less than five days. These figures would seem to point to rather better results from the drug than those which were ordinarily obtained from salicylic acid. The oil of wintergreen was the preparation used, and it was administered several times a day in ten-drop doses in flax-seed tea, which made it less disagreeable to the taste and to the stomach. In some of the cases the alkaline treatment was employed at the same time with the gaultheria.

Dr. Ball remarked that Dr. Kinnicut had used the oil of gaultheria in a number of cases of acute articular rheumatism in St. Luke's Hospital, and with even better results than those mentioned by Dr. Flint. The drug was administered in milk, and was less disagreeable when taken in this manner than salicylic acid or salicylate of sodium. Dr. Ball thought that the action of the medicine was like that of the two latter.

STRICTURE OF THE FEMALE URETHRA TREATED BY DIVISION.—Dr. F. N. Otis related two cases as follows. The first patient had suffered severely for some time, and had received a variety of treatment for difficulty in urination, but had obtained very little relief. Upon examination, Dr. Otis found that there was a urethral stricture admitting about a No. 18 French sound. He also struck a stone in the bladder. There was cystitis. The stricture was divided to 36 mm. with the dilating urethrotome, the finger was then passed, and careful search was

made for the stone, but it could not again be discovered, probably having been concealed in the folds of the bladder, for a few days afterward a stone of small size was passed with the urine.

In the second case the stricture was evidently the result of gonorrheal trouble, which had manifested itself within a week or two after marriage, and had continued for some time thereafter. Cystitis developed, stricture was suspected, and bougies had been passed, but they gave rise to so much pain that their use was discontinued. Dr. Otis found upon examination that there was a stricture, as in the first case, of about 18 French, which he divided, also with the dilating urethrotome, up to 36 mm. The cystitis disappeared entirely within a few weeks. Her physician was advised to pass sounds from time to time subsequently, to guard against recontraction; but, as the procedure gave her some pain, this was neglected, and recontraction took place within a month down to 26 mm. As the patient objected to another cutting operation, Dr. Otis passed the urethrometer again and turned it up to 36, and drew it out at that size. The pain from this procedure was not great; the bleeding was quite free, but soon ceased. Since that time the patient had been greatly relieved from trouble in urination. It was feared, however, that contraction would again take place. Dr. Otis remarked that these were the only two cases of well-defined stricture of the female urethra which he had seen.

Dr. Post recalled three cases of stricture of the female urethra, two of which he treated by dilatation and the other by incision, with satisfactory results.

Dr. Otis added that there had been no trouble from loss of power in the sphincter vesicæ in either of his cases. In another case in which he performed dilatation for the purpose of removing a stone he introduced his finger as far as possible, and the lady, who was about sixty years of age, suffered for six months afterward from slight incontinence of urine upon suddenly sitting down or coughing severely. Ordinarily, the sphincter was efficient, and it finally regained its power altogether.

Reports on the Progress of Medicine.

QUARTERLY REPORT ON DERMATOLOGY, SYPHILOGRAPHY, AND GENITO-URINARY DISEASES.

NO. XIV.

BY EDWARD BENNET BRINSON, M.D.

THE ORIGIN OF CANCER. In RETROSPECT, this subject was a topic for discussion at the last meeting of the British Medical Association ("Brit. Med. Jour.," March 24, 1883), Mr. Hutchinson managed, as he always does, whatever the topic, to invest it with a particular interest. With regard to the local origin of cancer (using the term in a broad sense for all forms of malignant disease), Mr. Hutchinson's views were advanced and very positively and clearly stated. He is unwilling to admit that cancer should be ranked as strictly a constitutional disease. It is urged that diseases are not necessarily constitutional because capable of inheritance. While heredity may perpetuate a proclivity to the disease, it gives no clue to its mode of origin. Using the writer's own words, "the laws of inheritance—as with property so with disease—concern convection, and not origin or production. The inheritance of a disease is a very different thing from its perpetuation, and gives no clue as to how that may have been accomplished." Thus heredity is not regarded as in any way a source of cancer.

Sir James Paget, in his unobscured remarks, when agreeing

in the main with Mr. Hutchinson's position, was disposed to attach a larger share of importance to the "constitutional element," implying that it is probably a more constant factor than is generally obvious, and he referred to the common difficulty of tracing back hereditary influences for more than a generation or two.

According to Hutchinson, there are two causes of the origin of cancer. One is senility of tissue—a predisposing cause—and the other local irritation—an exciting cause.

In connection with the generally admitted fact that cancer is, with few exceptions, an appanage of old age, the writer observes that the disease may result from local senility of the particular organ or structure concerned as well as from senility of the individual. The disease is peculiarly liable to attack an organ, such as the female breast, at a period when, its function having become obsolete, it begins to undergo senile decay. "Conditions of advanced senile atrophy" are less apt to give rise to cancer than the changes incident to the inception of these conditions. In a similar way may cancer develop in "moles or other innocent forms of new growths that run their course of development more rapidly than in normal tissues," or where it succeeds to a long-continued local inflammation, by exhausting the vitality of the part and inducing a premature senility. The interesting fact is adverted to that cancer has been observed in the lower animals only among those that have become domesticated, and of which the natural longevity has been increased by artificial protection.

With regard to the second or exciting cause of cancer, the writer adduces a number of facts as illustrating the manner in which, from purely irritative processes, by gradual and insensible gradations, the cancerous disease may finally be evolved. In this connection an interesting parallel is drawn between the processes of simple inflammation and those of cancer. The infective nature of the latter, which is sometimes regarded as characteristic, is shown to be common to both. The most essential point of difference is found in the fact that while one is amenable to the action of drugs and curable, the other is almost insusceptible to therapeutic measures and incurable. But between the two there is no distinct line of division where we can say the benign process ends and the malignant begins. As representing links between them, the writer mentioned instances of syphilitic gummous disease merging into cancer, rodent ulcer, and the *esthiomène* of Huguier. With regard to the two latter diseases, Dr. Thin was disposed to take issue with Mr. Hutchinson, asserting that in the case of rodent ulcer the evidences of true cancerous changes were as decided as in any other form of cancer; to which Mr. Hutchinson objected that, while the statement was true so far as the advanced stages of the disease were concerned, there was a stage when the diagnosis was no better revealed by the microscope than by the clinical appearances. Concerning *esthiomène*, Thin maintained that histological evidence of cancer was wholly obscure, but Hutchinson, in his rejoinder, assumed that the malignant course which the disease pursued justified the diagnosis of cancer in the broad sense he had given the term, notwithstanding that the histological signs were lacking.

As to the precise nature of the changes that constitute the difference between cancerous and inflammatory formations, Mr. Hutchinson ventured only to express an opinion favorable to the theory that the malignant process consisted in a "local reversion to fetal modes of growth," the epithelial cells returning to an embryonic state, which might suggest an analogy between this state induced by the local "senility" of cancer and the "second childhood" of old age.

Thin, who rejects this theory as based upon insufficient evidence, favored the hypothesis "of feeble differentiation of the

epithelial layers in the embryo. According to this theory, the liability to cancer must be carried back to the earliest stage of embryonic life, when one set of cells took on the epithelial character, and another that of the connective tissue. If, at this period, the vital qualities of the epithelium were feebly developed, the epithelial structures would, throughout life, be liable to take on perverted action under causes more or less slight. Local irritation would be liable to cause cancerous growths in persons whose epithelium had remained permanently weakened by original fault of development."

With reference to the more practical as well as most essential points of the paper, little or no dissent was expressed in the discussion that followed. All were agreed that there was a preliminary stage in the cancerous process; or, to use the writer's own phrase, "a precancerous stage," an early recognition of which was of the greatest importance.

ANOMALOUS RASHES.—At a meeting of the Clinical Society of London, in April last ("Lancet," April 21, 1883), Dr. Whipple reported two cases of typhoid fever which were preceded by scarlatinoid rashes. The evidences, both ante- and post-mortem, of the disease, being enteric fever, were decided, but the question was raised as to whether the rashes were due to scarlet fever preceding the typhoid, or whether they were anomalous forms of eruption due to the latter disease.

In the ensuing discussion, Dr. Mahomed remarked that he had seen rashes which he termed "roseolous" in the early stage of typhoid. He distinguished four kinds of rashes in typhoid fever, viz., "roseola, rose spots, *taches bleuâtres*, and miliaria."

Dr. Cavafy observed that the fact stated in connection with Whipple's cases—that the eruption had not been followed by desquamation—was not conclusive with regard to its being a case of scarlet fever, for he had seen free desquamation follow an erythematous eruption due to salicylate of sodium.

[It is by no means a very uncommon thing to see, either at the inception or during the course of an acute febrile affection, a roseolous or erythematous rash that is not characteristic of the disease, but is evidently of reflex origin. Such are the roseola typhosa, the roseola variolosa seu erythema variolosum, the roseola vaccinia, the roseola cholera, and the like.]

Dr. Andrew Clark referred to the so-called "doctor's rash"—the erythematous eruption produced in nervous patients when stripped for examination—as showing the influence of the nervous system in producing such rashes.

TACHETIC SYMMETRICAL GANGRENE.—At a meeting of the Clinical Society of London, in April last (*ibid.*, May 5, 1883), Dr. Southey reported the following case: The patient was a child nine years of age—emaciated, with a dry skin, and in an excitable, semi-delirious state. The pulse was 148 and feeble; respiration, 32; temperature, 99° F. No cardiac, lung, nor other visceral disease. The extremities were cold, and the patient suffered from insomnia. The right index finger showed a spot of gangrene at its tip. After a few days, the thumb and second finger of the right hand became red, throbbled, then livid, and finally gangrenous. Later on, exactly similar spots appeared on the pinna of the right ear, on the extremity of the nose, and the tip of the middle finger of the right hand. A little later, "subcutaneous mottlings (*tachettes*)" appeared all over the trunk and limbs, and "developed into a raised rash, like *urticaria tuberosa* or *erythema tuberculatum*." The spots itched and became tender, but gradually subsided, leaving only pigment stains. Finally all the fingers and the thumb of the right hand became gangrenous and slowly separated; also the thumb, index and little finger of the left. Extreme prostration supervened, with double broncho-pneumonia. A month later the child suffered from intermittent, true *hamaturia*. This disappeared, and the child finally recovered.

SALICYLIC PASTE.—Oscar Lassar ("Monatsh. f. prakt. Dermat.") recommends for cases of eczema which show an intolerance of ointments a paste composed of equal parts of oxide of zinc and starch powder with vaselin. To this paste are added various medicaments, but, as especially useful, salicylic acid is recommended. The advantages of the preparation over the ordinary salves are stated as follows: It does not liquefy at the ordinary temperature of the body, but dries on the skin, to which it adheres so closely, wherever applied, as to render a retaining bandage unnecessary. On hairy portions of the body it is objectionable, because of its sticking the hairs together. The zinc-starch paste has no irritating properties whatever, and is well borne when simple vaselin is not. The greatest advantage, however, is said to be due to its porosity, by means of which any secretions which arise from the surface to which it is applied are absorbed instead of collecting beneath it, as is the case with ordinary ointments.

It is claimed that the addition to the paste of salicylic acid in the proportion of two per cent. adds very decidedly to its curative effect in eczema.

The following is the formula:

R	
Acid. salicyl.....	2.0 (grs. x),
Vaselin.....	50.0 (℥ iv),
Zinci oxid.,	
Amyli.....	aa 25.0 (℥ ij).

M. Leniter terend. fiat pasta.

Letters to the Editor.

ADVERTISING AND THE CODE QUESTION.

SANDY HOOK, CONN., June 27, 1883.

To the Editor of the New York Medical Journal:

Sir: The inclosed slip was cut from the local column of the "Newtown Bee," issue of June 22:

"Dr. . . . of the Manhattan Eye and Ear Hospital, New York, will be in town next week to perform an operation. Persons who wish to consult a specialist in eye, ear, or throat diseases, can see Dr. . . . at Dr. Smith's office on Tuesday, the 26th."

The writer would like to be informed whether this style of advertising is the result of the new code, or a specimen of the "gentleman's code"? If of either, I prefer to remain an

OLD-CODE MAN.

* * * As the slip sent by our correspondent is said to have been taken from the "local column" of the newspaper in question, it may not have been inserted as an advertisement, but by the editor as a piece of news. Nevertheless, the individual whom it concerns, whose name we refrain from publishing, must not conclude that the profession in New York, whatever their opinions on the code question, look upon such announcements as anything short of detestable. Our correspondent ought to know that the code controversy has nothing to do with the matter, for, if anything, the new code is more stringent in all requirements not pertaining to consultations than the old code. Even the "gentleman's code" would not tolerate such a gross breach of taste.

DAMAGES CLAIMED FOR VACCINATION.—During the compulsory vaccination ordinance lately in force in Baltimore, one George W. Watts was committed to jail in default of payment of a fine of one dollar imposed for refusing to be vaccinated. He was exonerated at the jail, under a regulation requiring it, and now brings suit against the city and against the jail authorities for false imprisonment and forced vaccination, claiming damages in \$10,000.

New Inventions, etc.

A NEW UTERINE REPOSITOR

By ALFRED I. CHAMBERLAIN, M. D.
NEW BRIGHTON, N. Y.

The accompanying woodcut depicts a device, the invention of Messrs. Tiemann & Co., which possesses the advantage of continuous

and perfectly controllable application of power. Its construction is so simple that a glance at the engraving will render unnecessary any detailed description.

Miscellany.

ALBUMINURIC RETINITE OF PREGNANCY.—Dr. ROBERT H. TEMPLE writes: "Mrs. E., aged twenty-two, was referred to me by Dr. Temple on June 1, 1881, with the statement that the urine contained a large amount of albumin. The patient stated that she had been having blood in her urine for about a month. She also complained of headache, but not the vertigo, and complained of attacks of light in the eyes. She had been having vomiting occasionally. She had no pain in the eyes. There was a great deal of nausea and vomiting. She was in the fourth month of her pregnancy. With the microscope, the urine showed at five feet and read 20 Jäger. With the ophthalmoscope I observed, in the right eye, a somewhat irregularly shaped area of pale about the yellow spot, with numerous patches scattered about the retina. The optic disc was somewhat swollen and indistinct in its outline. The appearances in the left eye were very similar, with the addition of a small amount of hemorrhage in the fundus. On June 10, Dr. Temple informs me that, shortly after this, she was seized with convulsions and lost consciousness. She recovered, however, and, when I saw her again on August 10, the amount of albumin in the urine had greatly diminished, the scattered patches were less marked, but reticulate patches in the region of the macula were about the same as

when first seen. In the right eye, two veins apparently contained thrombi. The vision was, with the right eye, $\frac{38}{60}$, 16 Jäger; with the left eye, $\frac{20}{60}$, 16 Jäger. She could manage to write a letter. From Dr. Temple I learn that she regained good vision, but did not myself see her again. In a few months the unfortunate woman became pregnant again, although warned of the danger; convulsions supervened, and in one of them she died. *Remarks*.—It would be of considerable interest to learn in what proportion, and in what class of cases of albuminuria of pregnancy, retinitis occurs. That it does not necessarily occur, I know, having attended, some years ago, two cases in which there was no complaint of trouble of vision. One case, a woman of about thirty years, in her fourth pregnancy, made a good recovery. The other had uræmic convulsions, and died. I did not use the ophthalmoscope, but relied upon the patient's statements, the cases having occurred in my preopthalmoscopic days."—*British Medical Journal*.

MALARIA IN ITALY.—The Italian Minister of War has published a statistical map, based on the official reports from the different provincial governments about malaria, by which the extent and the intensity of this disease can be estimated. Italy counts 69 provinces, 6 of which only are completely free of this pest; in 21 provinces its ravages are most severe. It has been calculated that more than 40,000 soldiers every year have to pay their tribute to this terrible scourge. Malaria causes to the State an annual expense of two million dollars through the necessity of maintaining a number of hospitals expressly for malaria patients. The damage to the national wealth can not be calculated, but is immense; hundreds of thousands of working people in their best age are seized by the disease, and large tracts of else fertile country have to be left uncultivated. A very remarkable feature is the progress and the greater violence of the disease since the construction of railways, which circumstance is ascribed to the necessary earth-cuttings and the baring of stagnant waters. There are, in fact, some lines along which the strongest, healthiest workmen or officials stationed there are unable to resist the attacks of fever; the consequence is that the requisite working staff can be kept up with great difficulty, in spite of the exceptional high pay allowed to the men.—*Scientific American*.

SUBGINGIVAL INJECTION OF CHLOROFORM IN TOOTHACHE.—Dr. Guillot states, in the "Progrès médical" for March 24th, that he has very successfully pursued the practice, introduced by Dr. Dop, of Toulouse, of injecting chloroform into the gingival submucous tissue in toothache, which proves far more effectual than the injection of morphia. He fills a Pravaz's syringe about half full, and introduces the cannula parallel to the body of the jaw, carrying it to a depth of about two centimetres and a half, so that it almost disappears amid the tissue. No inflammation or ulceration has ever followed the injection.—*Med. Times and Gazette*.

A SIRENIFORM FÆTUS.—Dr. Raverty ("British Medical Journal") relates the following case of monstrosity: "I was called to attend Mrs. E., in her fourth confinement, on May 9, 1883. On my arrival I found the water had come away about twenty minutes before, and projecting from the os externum was a fleshy mass so unlike any usual presenting part of the fœtus to the touch, I was quite at a loss what to make of it. However, another pain coming on solved the riddle at once, the feet and leg or legs being expelled; and in a short time the shoulders and head followed. The child was alive, and continued so for eight hours. The mother made a good recovery. From the head downward to about midway between the sternum and the umbilicus it was in every respect well formed, and, to outward appearance, perfectly natural. From about that point the following particulars were noticed. There were no projections at the usual site of the crests of the ilia. The abdominal cavity was small, and seemed to be almost destitute of contents. The genito-urinary organs were represented by a small round aperture surrounded by a slightly elevated fleshy ridge. The limbs were inclosed in one continuous fold of integument, although the bones could be felt quite separate underneath; and in front there was a slight depression marking where the division ought to have been between the limbs. There was no separation of the

buttocks; in fact, there was very little of the usual projections at this point, and there was no anal orifice. The feet were joined together at the heel, and partially so at the center of the foot, but the toes were well formed, in the usual number, and free. I would have liked a post-mortem examination, but the parents objected. The mother said she had only gone eight months. There was no history of a fall or fright, except a bad dream about the fourth month."

THE LAW OF COMPENSATION.—"Puck" says: "And now the doctors smile at the prospect of business bracing up a little, for as pneumonia folds up its tent and floats silently off into the mystic past, the young man falls off his bicycle and breaks his collar bone."

THE TACTICS OF THE AMERICAN MEDICAL ASSOCIATION.—The "Philadelphia Medical Times" concludes an editorial article as follows: "We can not, however, close without a word of praise for the dexterity which was shown at the American Medical Association in so straggling all ethical rebels that none of them succeeded in crossing the sacred Æsculapian threshold, and the shades of Hippocrates suffered no dishonor, no distress over unseemly bickerings and disputings."

ARMY INTELLIGENCE.—*Official List of Changes of Officers of the Medical Department, United States Army, from June 9, 1883, to June 23, 1883.*—TILTON, HENRY R., Major and Surgeon. Granted leave of absence for four months. S. O. 136, par. 7, A. G. O., June 14, 1883. — APPEL, AARON H., First Lieutenant and Assistant Surgeon. Relieved from duty in the Department of Dakota and assigned to duty in the Department of the East. S. O. 130, par. 3, A. G. O., June 7, 1883. — POWELL, JUNIUS L., First Lieutenant and Assistant Surgeon. Relieved from duty in the Department of Texas, and assigned to duty in the Department of the East. S. O. 130, par. 3, A. G. O., June 7, 1883. — RICHARD, CHARLES, First Lieutenant and Assistant Surgeon. Relieved from duty in the Department of Dakota, and assigned to duty in the Department of the East. S. O. 130, par. 3, A. G. O., June 7, 1883. — GORGAS, W. C., First Lieutenant and Assistant Surgeon. The leave of absence granted in par. 5, S. O. 51, C. S., Department of Texas, extended one month. S. O. 63, Military Division of the Missouri, June 19, 1883. — WYETH, M. C., First Lieutenant and Assistant Surgeon. Assigned to duty at Fort Maginnis, M. T. S. O. 103, par. 2, Department of Dakota, June 14, 1883.

NAVAL INTELLIGENCE.—*Official List of Changes in the Medical Corps of the Navy for two weeks ending June 23, 1883.*—Surgeon Edward Kershner, from Marine Barracks, Brooklyn, to the Navy Yard, Brooklyn. — Medical Director John Y. Taylor, from the Naval Hospital, Washington, to the Naval Hospital, Norfolk, Va. — Medical Director James Suddards, from the Naval Hospital, Norfolk, Va., and waiting orders. — Medical Director T. J. Turner, from the National Board of Health, and waiting orders. — Medical Director Charles Martin, from the Navy Yard, New York, and awaiting orders. — Medical Inspector John C. Spear, from the Naval Medical Board to the Navy Yard, New York. — Assistant Surgeon Oliver Diehl, United States Practice Ship Dale, to report to the Medical Board for examination, preliminary to promotion. — Medical Inspector David Kindelberger, and Medical Director F. M. Gunnell, to the Retiring Board. — Passed Assistant Surgeon M. H. Crawford, from the Navy Yard League Island, Pa., to the United States steamer Pinta. — Surgeon Jerome H. Kidder, resigned, to take effect June 18, 1884, and granted leave till that time. — Medical Director Thomas J. Turner, orders of the 7th June modified to continue on duty as a member of the National Board of Health till June 30, 1883.

SOCIETY MEETINGS FOR THE COMING WEEK.—*Monday, July 2d*: Utica Medical Library Association. *Tuesday, July 3d*: Elmira Academy of Medicine; Buffalo Medical Association; Ogdensburg Medical Association; Croton Medical and Surgical Union (Katonah, N. Y.—annual); Medical Society of the County of Hudson, N. J. (Jersey City); Medical Society of the County of Union, N. J. *Wednesday, July 4th*: Medical Society of the County of Richmond, N. Y. (Stapleton—annual). *Thursday, July 5th*: Society of Physicians of the Village of Canandaigua, N. Y.
